It may be claimed that to replace ordinary gas in an existing plant by acetylene would be making use of a plant much too cumbersome for the purpose, and that the interest on capital investment and depreciation would count more heavily against the acetylene than in a plant specially constructed for the purpose. On the other hand, in a plant specially constructed for acetylene, the system of mains for transmission of the gas would have to be laid with much more care than for ordinary illuminating gas, and special piping might have to be used, so that the capital investment of a specially constructed acetylene gas plant might be as much or more than for one furnishing ordinary illuminating gas.

If one-tenth as much acetylene were used for a given illumination as with the ordinary gas, then, if transmitted through the same system of pipes, the percentage of leakage, based on the amount of gas used by the consumers, would be increased about tenfold; or, if the percentage of leakage in a system had been 5 per cent. with ordinary gas, it would be about 50 per cent. with acetylene, of the gas used by the consumers, or 33 per cent. of the gas stored in the holder.

The system of piping now in place for ordinary illuminating gas would not, therefore, be suitable for the transmission of acetylene gas. If special pipes were laid for the acetylene gas they would be required to carry a less volume of gas for a given illumination, and could be made smaller, but it is probable that the care required to produce tight joints would make it just as expensive to lay them as to lay the pipes for ordinary illuminating gas.

Let us next consider the price calcium carbide must be sold at to take the place of kerosene in domestic lighting, where the gas is generated on the premises. Assume that the cost of labor to charge the gas generator, and depreciation of the plant, is equal to the cost of labor to fill and repair the oil lamps; then we have to compare the cost of the carbide with the cost of kerosene oil required to produce an equal illumination. It was found by my own experiments that to produce 16 candle-power in an argand, or in a good flat flame lamp required about 0.002 gallon of oil per hour. At 8 cents per gallon this would cost 0.18 cent. To produce 16 candle-power with acetylene requires 0.4 cubic feet of gas per hour, so that 0.4 cubic feet would have to be produced for 0.18 cent, or 10,000 cubic feet for $45. Hence, the carbide would have to be purchased for $45 per ton to be as cheap for equal illumination as kerosene oil. As one pound of the compressed liquid acetylene produces about 14½ cubic feet of gas, it would have to be sold for 6½ cents per pound to be as cheap for a given candle-power of light as kerosene.

---

* The cost of gas stored in the holder is less than 40 cents per 1,000 cubic feet in many large plants, and the price that the gas companies could afford to pay for the carbide would be proportionally reduced. For example, if the gas were stored in the holder for 30 cents per 1,000 cubic feet, the carbide would have to be furnished to the gas company and converted into gas for $30 per ton, to be as cheap as ordinary gas burned in flat-flame burners.

In some of the earlier literature on acetylene it was proposed to convert electric lighting plants into plants for the production of acetylene, and thus obtain economic results. This could not be done economically, for only about one-half as much light could be obtained from the acetylene as by using the electricity direct for incandescent lights. The results obtained at Spray show that 2 cubic feet of acetylene gas could be produced per hour per electrical horse-power. This would furnish $2 \times 40 = 80$ candle-power. If the electricity were used direct with incandescent lamps requiring 4½ watts per candle-power, the light produced would be $746 \div 4.5 = 166$ candle-power per electrical horse-power, or about twice as great a light as would be produced by the acetylene, as has already been stated.

To be as cheap an illuminant as electricity, therefore, the carbide must be made at some point, say, a water-power, where the cost of the power and attendance is much less than at the lighting station.

It has been shown that for an equal illumination the electric incandescent light costs twice as much as gas when the latter is burned in flat-flame burners. The incandescent electric light has, however, held its own against the gas light on account of its superior qualities, which are its brilliancy, cleanliness and adaptability. The electric light is also preferable on account of the fact that it does not vitiate the atmosphere with carbonic acid gas, and that it produces a less heating effect than ordinary illuminating gas. It also eliminates the danger of asphyxiation through an accidental leakage of gas. That the incandescent electric light has held its own at a higher cost to the consumer for a given candle-power, is a proof that other elements enter into the problem of artificial lighting as strongly as the cost of a given amount of light. From this standpoint, it may be argued that acetylene, producing as it does a more brilliant light than any now used for interior lighting, and having the quality of showing the complexion in life-like tints, will have its own field, even should it be the most costly style of illumination.

Again, acetylene is now used in place of the calcium light for lantern projections, etc. Were it not for the explosive character of the compressed acetylene, it would be useful for cases of isolated lighting, such as for beacons and light-buoys.

It has also been shown that the Welsbach lamp produces about three times the illumination for a given cost as ordinary illuminating gas burned in a flat-flame burner, but that it is deficient in showing the complexion in life-like tints. For most classes of work, this defect is not of great enough importance to outweigh the advantage derived from its great economy.

The whole situation may be summed up by saying that each system of lighting has its own field of usefulness, on account of properties peculiar to itself, which make it more desirable than the others for certain classes of work.

CURRENT BOILER PRICES FOR LARGE ELECTRICAL PLANTS.

OUR Washington correspondent sends us the following account of the bids for boilers received by the United States Electric Lighting Co., of Washington, D. C. The bids were opened publicly on May 5.

The specifications called for six boilers of 3,000 square feet of effective heating surface each, erected complete, including all mason work, and ready for all connections. The following are the bids submitted by the different competing companies:

Abendroth & Root Mfg. Co., for six boilers, each having a rating of 288 h. p., equipped for hand firing, $24,448; equipped with American stoker, $29,448; equipped with Hawley down draft furnace, $30,948; equipped with Roney stoker, $30,508; equipped with Acme stoker, $30,948.

The Babcock & Wilcox Co. submitted bids for six boilers, having a total heating surface of 18,126 square feet, equipped for hand firing, $17,452. For the addition of the following named stokers and furnaces, add the following amounts: For Hawley down draft furnace, $1,375 each; Babcock & Wilcox chain grate, add for six boilers, $9,060; for total equipment with Roney stokers, add $6,360; for total equipment with Murphy stokers, add $7,350. These bids include steel heater construction.

Messrs. Thayer & Co. submitted bids and specifications for six boilers of the Babcock & Wilcox type, containing a total of 17,857 square feet. These boilers were to be equipped with their flowed steel headers. For equipment for hand stoking, the bid for six boilers was $20,000. If equipped with Hawley down draft furnace add $1,375 per boiler. If equipped with Acme stoker, add $6,500 for six boilers. If equipped with Roney stoker, add $6,060 for six boilers. This company stated further that a deduction of $500 would be allowed for furnace fronts and grates in case any of the above stokers were used.

Messrs. Thayer & Co. also submitted a bid for six Cahall vertical boilers, erected complete, including a separate stack for each boiler. Their bid for these boilers was $20,000, and in case stokers were to be used in connection with these boilers, $500 was to be deducted from the above price for fronts, etc. This company made a guarantee when using George's Creek coke, containing not less than 13,000 B. T. U. per pound, with boilers operating within 25 per cent. above their rated capacity and efficiency of 70 per cent., and when the boilers were being crowded to 75 per cent. above their rating they would develop 60 per cent. efficiency.

The Heine Boiler Co. submitted a bid for six boilers, each having 3,048 square feet of heating surface when equipped for hand firing, $23,900. These boilers when equipped with Hawley down draft furnace, add $8,190 to the above figure. When equipped with Roney stoker, add $6,000 to the above figure. When equipped with Acme stoker, add $6,440 to the above figure.

The Campbell & Zell Co. submitted a bid on six boilers to conform to the requirements of specifications, equipped for hand firing, $24,102.93; when equipped with Murphy stoker, $31,410.93; when equipped with Acme stoker, $31,089.93; when equipped with Roney stoker, $30,591.93; when equipped with Hawley down draft furnace, $32,891.93.

The Edgemoor Boiler Co. submitted a bid on six boilers, each containing 3,008 square feet of heating surface, when equipped for hand stoking, $25,000; when equipped with Acme stoker, $30,094; when equipped with American stoker, $30,844; when equipped with Hawley down draft furnace with extension front, $32,872; when equipped with Hawley down draft furnace with flush front, $31,554; when equipped with Murphy stoker, $31,120; when equipped with Roney stoker, $30,674; when equipped with Vicar's stoker, $30,204; when equipped with Wilkinson stoker, $29,100.

Gill Boiler Co. submitted a bid on six boilers, each having a rated capacity of 300 h. p., for $19,500, when equipped for hand firing. No mention was made of addition of stokers in this bid.

National Boiler Co. bid on six boilers, having a total rated capacity of 1,800 h. p., when equipped for hand stoking, $18,200. In case steel cast headers were required, add $3,925 to this figure. When equipped with Murphy furnaces, add, for six boilers, $6,750; when equipped with Roney furnace add $6,060; when equipped with Wilkinson stoker add $6,000.

The Phoenix Iron Works submitted a bid for eight boilers, presumably of the shell type, each having a rated capacity of 250 h. p. These boilers, when equipped with Vicar's stokers, $40,000.

The Columbian Steam Boiler Co. submitted a bid for six boilers, each containing 3,000 square feet of heating surface, equipped for hand firing, $27,000. No bids were made for addition of stokers.

The Clonbrock Boiler Co., manufacturing the Climax boiler, submitted a bid for six boilers, each having a rated capacity of 300 h. p., for $21,600. No stokers were mentioned in connection with this bid, the above figure being for hand firing.

The Caldwell Boiler Co. submitted a bid for six boilers, each having a rated capacity of 270 h. p., when equipped for hand firing, $18,820; when equipped with Murphy stoker, $26,170; when equipped with Roney stoker, $25,930; when equipped with Hawley down draft furnace, $27,070.

The Geary Boiler Co. submitted bid on six boilers, having a total of 18,000 square feet of heating surface, when equipped for hand firing, $24,300; when equipped with Hawley down draft furnace, $32,550; when equipped with Acme furnace, $31,000; when equipped with Wilkinson stoker, $30,500.

The Stirling Boiler Co. submitted bids on two different kinds of boilers, one of which they termed a No. 1 boiler, and the other was termed a No. 2 boiler. Each kind of boiler contained a total of 18,000 square feet of heating surface, and when equipped for hand stoking, the No. 1 boiler was submitted for $17,925; No. 2 boiler for $18,000. The Meisner stoker was offered with these boilers at an additional cost of $14,400 for the six boilers.

Robert Wetherill submitted a bid for seven Berry boilers, having a total of 18,000 square feet of heating surface, for $24,500. No mention of stoker was made in connection with this bid.

"We prize your paper very much, and feel that you have a great future. We also consider your articles very authentic. The feature of your Data Sheets alone has been a sufficient argument to place the advantages of your paper over other periodicals printed for people seeking knowledge." Northwest Electric Engineering Company, Portland, Ore.

ELECTRIC TRANSPORTATION

THE K. A. K. ELECTRIC SYSTEMS FOR STREET, ELEVATED AND TRUNK LINE RAILWAYS.

FOR the past year and a half there has been in practical operation at Springfield, O., a section of railroad equipped with the K. A. K. conduit system, which has given very good results.

The engraving, Fig. 1, shows a section of this line with a portion of the top removed with the trolley or contact plow lying at the side. Figs. 2, 3 and 4 show additional details of construction by which such an insulation resistance has been attained, that the leakage current for several hundred feet of conduit did not exceed .004 ampere.

Fig. 2 shows the detail of the conduit with the electrical equipment installed, demonstrating the ease with which the electric system could be introduced into a cable conduit. A is a cast iron yoke, in this case fitted with metal ties which support the track rails. B B are substantial insulators of special construction which support the iron pipes, C C, on the yokes, in which the insulated auxiliary feed wires D D are laid and which act as a support as well as a protection to them. The couplings for the pipe are so constructed as to also form a support for the conductor rails E E by means of the insulators F F. It will be seen that the feeders and conductor rails are both doubly insulated, making four heavy insulations through which the current must pass to form a short circuit; hence the slight leakage shown in the test above alluded to.

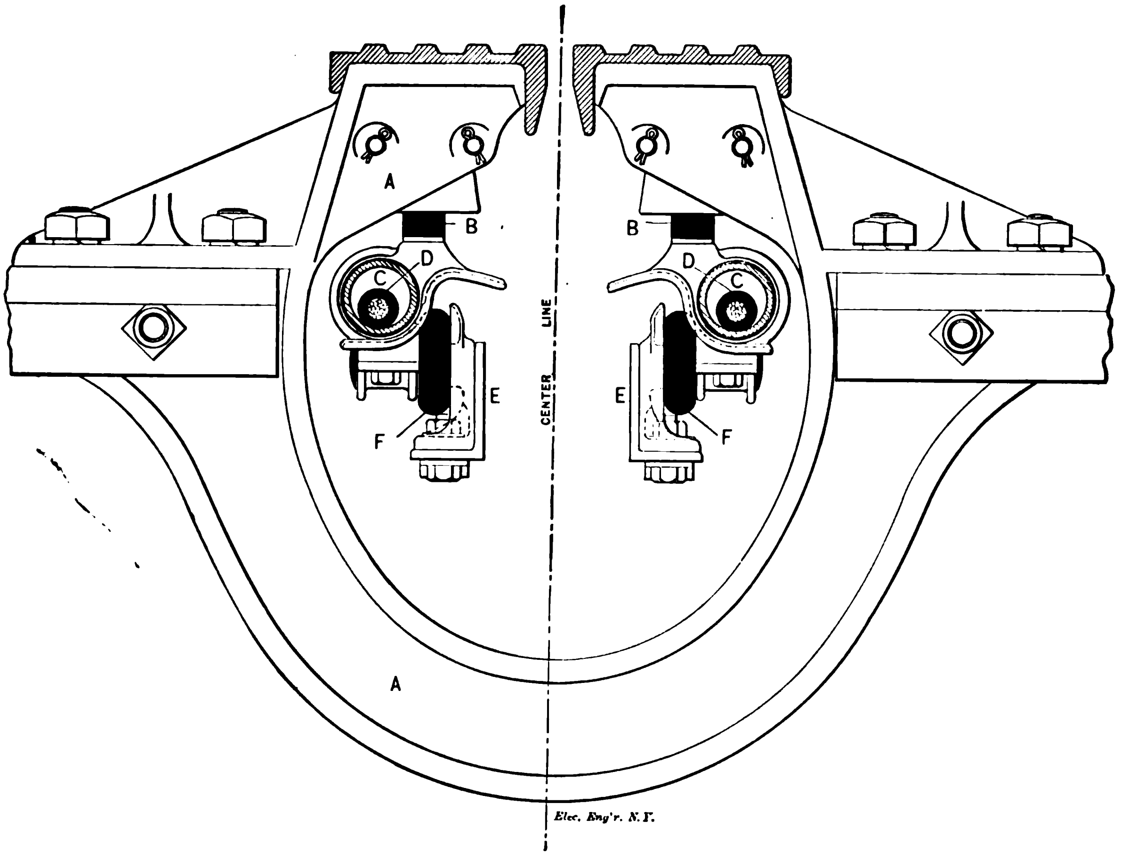

FIG. 2.—SECTION OF K. A. K. RAILWAY CONDUIT SYSTEM.

The conductor rails are of angle steel and are in sections of convenient length, say, 300 feet, and connected to the auxiliary feeders by fuses and plugs, as shown in Fig. 3. In case a short circuit should occur at any point the fuse would be blown on that section only, leaving all the remainder of the line in good working order, so that the ground would be quickly located and trouble easily repaired. At the end of the sections where the fuses are attached, the auxiliary feeders are deflected from the conductor rails, for safety, as shown in Fig. 3, manholes being provided for this purpose. Where there is a heavy traffic to provide for on a long line of road the main feeders can carry a current of 5,000 or 10,000 volts and at suitable distances by means of rotary transformers supply the auxiliary feeders D D at 650 volts.

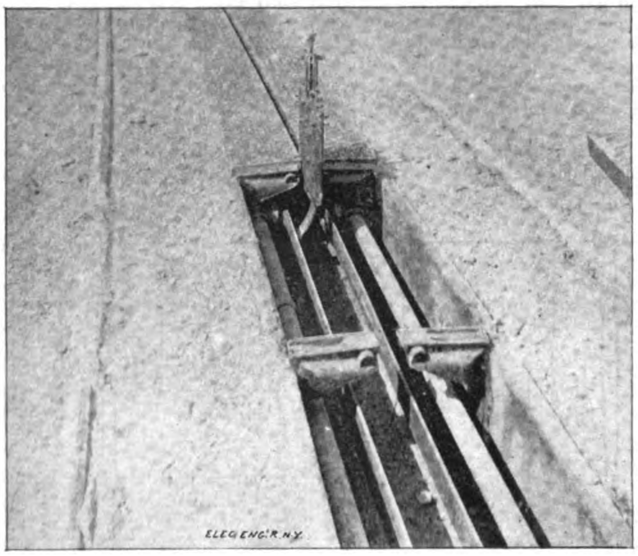

FIG. 1.—SECTION OF K. A. K. RAILWAY CONDUIT.

Fig. 4 shows a side and sectional view of a plow or contact device which can be made single or double, as required. A contact shoe, G, is supported on a spring H, which is so supported in the post I that it can be raised or lowered; and as seen in the sectional view, when raised, the shoe comes within the lines of the post, so that the whole can be lifted from the slot at any point along the line, making it possible to equip suburban cars having overhead trolleys, to be run over the conduit lines also, and where desired provision is made so that this change can be made without stopping the motion of the car. It will be noticed a heavy insulation of fiber or other suitable material is used in the post, and that is protected by hardened steel plates, so that the liability to short circuiting in the contacts is reduced to a minimum. It has already been fully demonstrated that electrical equipment possesses so great an advantage over steam in economy of motive power on elevated and surface railways, that to meet such conditions of traffic the K. A. K. third-rail system has been devised which is claimed to eliminate the two most serious obstacles in the way of equipping all roads now using steam power with electricity. These obstacles are the danger to life from an exposed third-rail conductor and the delays in traffic occasioned by sleet and snow in the use of the unprotected third rail. Our illustration, Fig. 5, shows a model section of the K. A. K. covered third rail, with the cover partly removed, showing an angle rail conductor A supported on posts S which are sustained in place, on the ends of the ties outside the track-rail by the cast iron sockets spiked to the ties the same as the track rails. A flange on the under side of the sockets fits into a groove in the ties; this groove is uniformly cut by gauge with the track rail so that ordinary trackmen can construct the line without mistake and do it accurately. The rail has the same capacity for carrying the current as other forms of third rail in use while the wooden cover C over the top and at the back of the post supports protect the rail in every way, at the same time keeping the posts (which are first treated by boiling in oil) dry and thus making them good insulators.

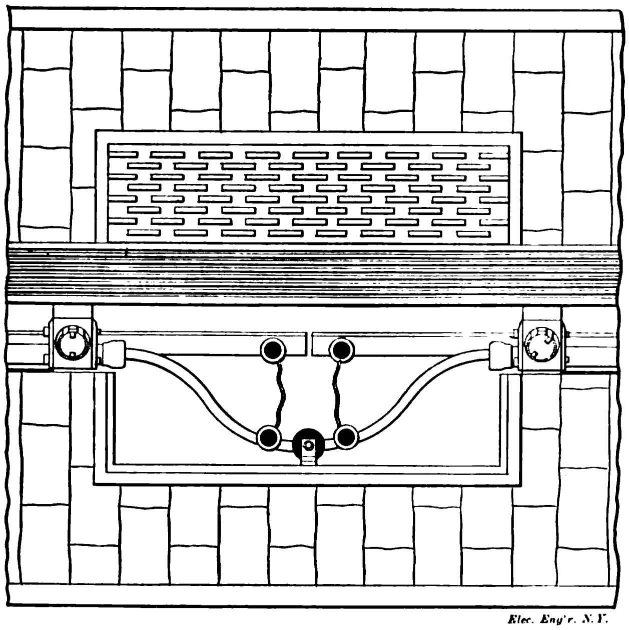

FIG. 3.—CUT-OUT BOX IN K. A. K. RAILWAY CONDUIT SYSTEM.

The contact shoe shown in Fig. 5 is supported from the truck of the car, by means of a spring and comes in sliding contact with the under and inner surfaces of the angle rail conductor, giving a good contact with any pressure desired.

At crossings or switches the covered third rail is cut out and the train passes over by coasting, or all the trucks of all the cars can be provided with contact shoes, so that those in the rear are in contact while those in front are making the crossing or switch.

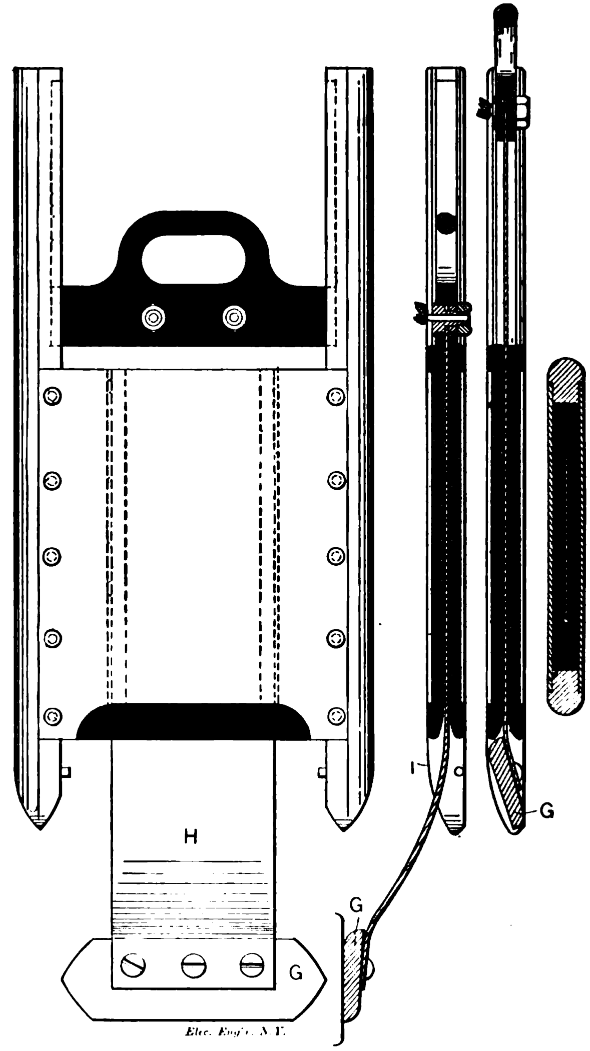

FIG. 4.—CONTACT SHOE OF K. A. K. RAILWAY CONDUIT SYSTEM.

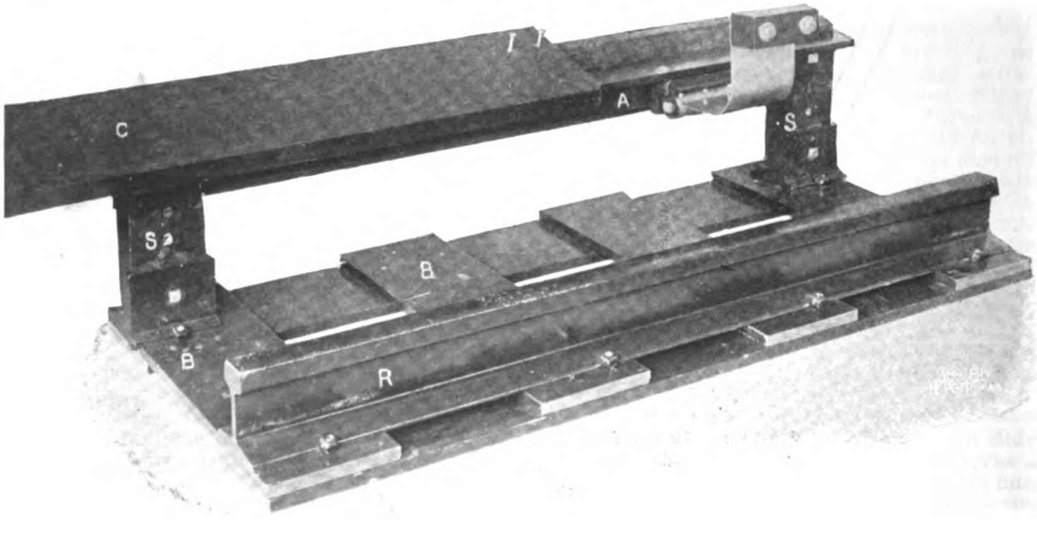

FIG. 5.—THE K. A. K. THIRD RAIL CONDUCTOR SYSTEM.

The K. A. K. systems, on conduit and covered third rail, are owned and controlled by the Hon. O. S. Kelly and A. S. Krotz, of Springfield, O., and W. P. Allen, of Chicago, and negotiations are now pending for their introduction on a number of roads.

HEATING OF ARMATURES.

BY GEORGE MOFFAT.

WHILE an armature has been defined as a bundle of wires cutting magnetic lines, with suitable connections for carrying off the induced current, it is this "bundle of wires" which is the vital part of our electric systems to-day and has given more trouble and study than all the rest of the system combined.

The working capacity of armatures may be said to be limited by two things, sparking at the brushes and heating of the armature itself. Of these the heating of the armature has been found the more troublesome of the two on account of the difficulty in overcoming it. To stop sparking at brushes, unless a structural defect, is much easier accomplished. Besides the element of risk accompanying undue heating we have a large waste of power, and power means money.

Fig. 1 is a diagram showing the waste in watts for different ranges of temperature in an armature carrying 2,000 amperes, tested by the writer. At the higher temperatures the power lost is surprising. The same machine showed a rise of 176 degs. Fahr. above surrounding temperature; it is with this rise that the diagram in Fig. 2 is plotted out to show the waste as the output of the machine is increased. There will also be increased permeability with increased temperature and as the machine tends to lose its load, if working in parallel, the attendant will in the majority of cases cut out resistance, thus making a machine carry the brunt of the load when it is least able to do so.

The cause of undue heating may be traced to any or all of the following: Hysteresis, eddy currents, insufficient ventilation, heating of the conductors themselves and in a few cases the friction of the brushes. That due to hysteresis is of course due to grade of iron and is purely a structural defect for which there is no excuse whatever; the only remedy being to use a good grade of soft iron.

Eddy currents are not so easily disposed of. Their wasteful nature and causes giving rise to the same are well understood by manufacturers of electrical machinery generally, who all claim to have overcome them. The well-known laminated core is adopted by all with laminations in direction of magnetization, so that the magnetic continuity may not be broken, and with varnish, paper, enamel or some other like insulating material used about every 10 or 12 laminations. With all these precautions eddy currents are mainly responsible for heat in the core.

Should metal supports of armature constitute closed circuits there will be wasteful currents contributing towards this injurious heating. Insulated tie-bolts are giving way to the much solider "harveyized" bolt in which there is no insulation to char and loosen.

As is well known it is at the periphery that the insulation is most needed on the discs; it is there also that it is the weakest. After being assembled the core is generally trued up, sometimes with a file and by others in a lathe. In either case the result is the same; the tools burr the edges until it is practically a solid mass.

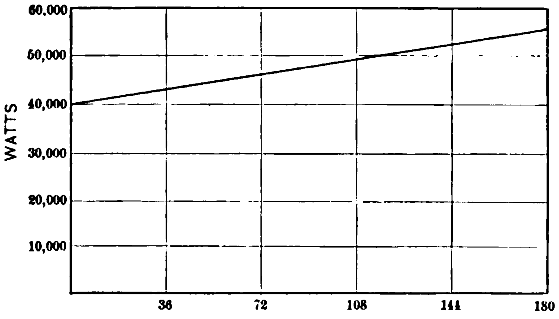

FIG. 1.—LOSS FOR DIFFERENT RANGES OF TEMPERATURE IN AN ARMATURE, LOAD 2,000 AMPERES.

In the machine referred to above, which had a rise in temperature of 176 degs. Fahr., the insulation could not, of course, last. One morning there was a pyrotechnic display and an armature to rewind. Before rewinding the engineer loosened up the bolts and made generous use of varnish on the discs. After the machine was started the improvement was startling; temperature dropped to about one-half for the same load.

Other machines in process of construction were treated likewise and with the same result.

If the ventilation is thorough and there are large radiating surfaces the heating from eddy currents will be greatly alleviated, but still there remains the loss of power. One abominable practice is that of putting canvas heads over winding. There was some excuse a few years ago for doing this—to hide poor workmanship—but now it should be religiously shunned. Immediately after a dynamo has stopped its temperature will rise as the fanning effect due to rotation of armature has ceased. This fact was accepted by one maker as a gentle hint for a remedy for his hot armatures. He at once put on his machine, back of armature and fastened on shaft, a set of sheet iron wind mill blades to blow a current of air through interior of the machine—a warning to all men to have nothing to do with that class of machines. The large, slow-speed spider armatures give the best result when ventilation alone is considered, as there is a greater surface exposed both of the iron and the conductors. But even with this it is simply the "cure" and not the "prevention" we have.

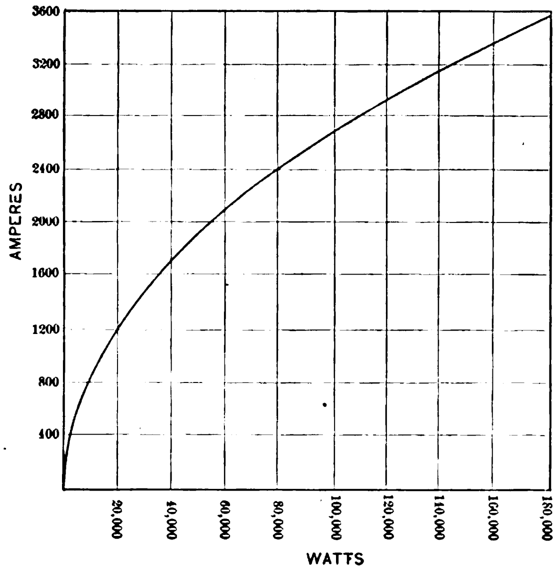

FIG. 2.—CURVE SHOWING LOSS OF POWER, IN AN EXCESSIVELY HEATED ARMATURE, FOR DIFFERENT LOADS.

Another fruitful source of trouble is the heating of the conductors themselves. The chief cause of this is working the machine beyond its true capacity—not its rated capacity—which may be very much higher. For a legitimate increase of temperature above that of the engine room 50 degs. Fahr. may be taken; for the highest permissible limit 90 degs. Fahr. is the maximum. The formula for calculating this, with 90 degs. as the maximum, is as follows:

$$\text{Maximum load-amperes} = 0.95\sqrt{\frac{S}{R}}:$$

In which S = number square inches surface of coils, and R = their resistance in ohms.

Even with this moderate increase of temperature the resistance is increased about 20 per cent. If a machine heats above this when running at its rated load its share of the work should be reduced until it comes within this limit.

In some machines tested it was necessary to reduce the load almost 50 per cent. before the above conditions were met with. The maker's guarantee that the machine's capacity is 100 per cent. above what is found safe will not bring back the power thus wasted.

The heating arising from the friction of brushes, if excessive, may be remedied by better brushes, springs no stronger than necessary to make perfect contact, a true commutator, and, if necessary, a little light bodied oil applied occasionally which will quicken the polish.

The main requisites for cool running would then seem to be, machines run at their true capacity, properly insulated, laminated cores and thorough ventilation.

PRESIDENT H. H. VREELAND, of the Metropolitan Street Railway Company, New York, states that the transfer system has reduced the average fare to 3.71 cents, and that more than 200 men are receiving an extra compensation of 25 cents a day because no complaint had been lodged against them by passengers or officers during the past year. The number is growing.

THE HISTORY OF A SAN FRANCISCO TROLLEY ROAD.

THE San Francisco and San Mateo Electric Railway, the first extensive line operated by electricity constructed in San Francisco, has been formally transferred to the purchasers under the foreclosure sale of a year ago. The time for redemption granted by the law to the original owners of the road expired over a week since. The road has, therefore, been at last rescued from its financial troubles, and it is now said that the new proprietors will expend some money in its improvement and development. Exactly when the work of reconstruction will begin is not stated; but from the fact that the enterprise can be made to pay handsomely upon the money now invested in it, it is reasonable to suppose that no time will be lost in putting it upon a sound mechanical basis.

The history of the San Francisco and San Mateo Electric Railway presents an interesting illustration of the vicissitudes of what the Populists call "corporation monopolies." The road was constructed primarily for the purpose of bringing certain lands in the outskirts of the city into the market. These lands were largely owned by Behrend Joost, who contributed in great part the money to build the road. A practical railway builder was brought out from the East, and the extensive trolley system which now operates the line was constructed. The work cast the corporation organized by Behrend Joost over a million and a half dollars. Joost is said to have contributed about $600,000 of this amount. The road was bonded for nearly or quite its full value and the bonds were sold extensively to local investors.

The boom period during which the railway line was conceived, however, subsided soon after its completion. The result was that sales of land fell off, and people did not appear to populate the real estate owned by Joost and his fellow land boomers. The road defaulted in its interest, a receiver was appointed and the bondholders began proceedings in foreclosure. The result of these proceedings show to what an enormous extent the value of the road shrunk between 1893 and 1895. The property sold by the sheriff brought $330,000, which included the rails, rolling stock and other equipments of the entire line. After deducting the receiver's fees, costs and attorneys' charges, there was left for the bondholders a dividend of just exactly 10 cents on the dollar. Those who invested one thousand dollars in the bonds of the road, had returned to them one hundred dollars.

A more complete financial wreck has rarely been seen, yet the road is a good property, and under first-class management can be made to pay. The trouble with it was that practical railroad men neither planned it at the beginning nor engaged in its management afterwards. There is no property so susceptible to bad management as railroad property. Wrecking a railroad is easier than wrecking a steamship, and it is well known that a captain can run the latter upon the rocks any dark night, and not suffer the loss of his certificate. However,; the San Francisco and San Mateo Electric Railway, now that its capital represents an expenditure of but little more than $300,000, ought to be made to pay a handsome dividend upon the investment. It is operated through a country which some time will support a dozen similar railways.—San Francisco "Post."

"HOG LANE"

At the meeting of the Somerset County (N. J.) Board of Freeholders, to consider the application of the New York and Philadelphia Traction Company, to be permitted to erect a bridge across the Raritan river at Bound Brook, for the purpose of laying a trolley line, the company asked that it be allowed to rest part of the structure on one side of the present bridge, in order to save the expense of an extra truss. Some of the members would not agree to that, but wanted to compel the company to erect an entirely separate bridge. Andrew Lane then arose and said that that would be too much like a story he had heard of two farmers who live near Bound Brook. Their farms join and it was necessary to erect a fence to divide the two properties. Ordinarily one farmer would have had to build half of the fence and the other the remainder. But they could not agree on the style of fence to be built, and the result was that two fences of different pattern were built, leaving a narrow space between. This strip is called "hog lane" in the surrounding neighborhood. "Now," said Mr. Lane, concluding, "we don't want any hog lane across the Raritan river."

The point struck the Freeholders forcibly and they unanimously agreed to give the company the grant they desired.

ELECTRIC ROAD FROM HOUSTON TO GALVESTON, TEX.

Engineer A. B. Blevins and party, now engaged in running the survey for the proposed Houston-Galveston Electric Railway, completed the survey from Seabrook to Dickinson bayou on April 20. The route as surveyed runs through the North Galveston tract lands a distance of about two miles and nearly parallels the Galveston, La Porte and Houston Railroad, being east of that line about half a mile. With the building of this road begins a new era in the matter of transportation in the State of Texas. This will be one of the largest roads of its kind in the United States, and it is the intention to make it one of the best. New York capitalists are said to be at the back of the enterprise, and a million and a half is in readiness awaiting the completion of the preliminary work. The building of this road means a rapid development of the country through which it passes; quick train service and low rates for both passengers and produce will make it a boon to farmers and city people alike. Of the three surveys the bay shore route stands a fair chance of acceptance. It is not difficult to understand why there are advantages to be gained in keeping near the water from Houston on down, as this entire strip is destined to be a great summer and winter resort as well.

MECHANICAL

THE PRINCIPLES AND CONSTRUCTION OF WATER WHEELS.—III.

BY W. E. WINES.

TURBINES are capable of using a large amount of water with great economy and develop their highest efficiency—about 75 to 85 per cent.—under rather low heads. Their excessive speed under high heads produces foaming and eddying of the water which involve large losses; the wear due to the presence of sand and grit in the water is also increased and causes rapid destruction of the wheel. The enormous static pressure due to a high head also necessitates greatly increased cost for flumes and penstocks.

To obviate all these difficulties a wheel known as the Pelton water wheel has been developed on the Pacific coast for use in the mountainous mining districts where high heads are the rule, not the exception, where the water is likely to contain large quantities of sand and other foreign matter, and where simplicity of construction and ease of transportation are necessary features.

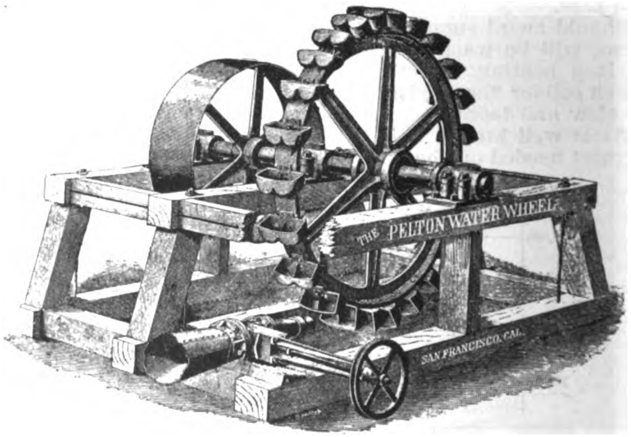

FIG. 7.—PELTON IMPULSE WATER WHEEL.

It may be briefly described as a vertical wheel having cups or buckets attached to its circumference against which a stream of water is directed by means of a nozzle, the whole being supported by a base requiring no expensive foundation and enclosed in a suitable case.

Fig. 7 shows one of these wheels, with cover removed, mounted on a wooden frame bolted together so that it may be readily taken apart for transportation. The flow of water may be regulated by the valve or in times of low or high water the tip of the nozzle may be changed. The bearings are not subjected to the action of the water and are at all times readily accessible. The most remarkable feature of this wheel is its high efficiency, 85 per cent. being in all cases guaranteed by the makers. The cause of this is to be found in the shape of the bucket.

It has been already pointed out that when a jet of water strikes a vane, the axis of the jet being perpendicular to the surface, that the water spreads out into a sheet and flows over the surface; but one fact of this phenomenon was not mentioned, namely, the formation of a cone of what may be termed "dead water" just at the point where the water strikes the vane. This is shown in Fig. 8. As this water does not flow over the surface its reactive effect is entirely lost, and the recurrence of this at every passage of a bucket through the jet entails a serious loss of energy. It is for this reason that the wedge, Fig. 9, has been made a part of the Pelton bucket. The curvature of the inner surface of the bucket is such that the direction of flow of the water is as nearly as possible completely reversed and the makers require that the speed of the periphery of the wheel be one-half that of the entering water thus conforming to the two cardinal principles which theory indicates are necessary for high efficiency. Experiments made at the University of California by Mr. Ross E. Brown, a well-known mining and hydraulic engineer, show conclusively the advantage of the wedge in the bucket. Wheels running under a head of 50 feet with a ⅝-inch nozzle gave the following efficiencies:

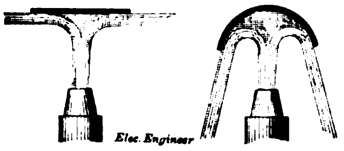

FIG. 8.

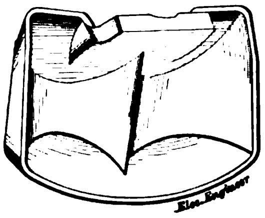

FIG. 9.

Flat vane wheel	40.4	per cent.
Curved bucket without wedge	65.6	" "
Curved bucket with wedge	82.5	" "

By varying the diameter of the nozzle, the size of the buckets, and the diameter of the wheel, the Pelton wheel may be adapted to meet the requirements of any particular case in regard to head and quantity of water available, power required and speed of wheel. Since the velocity of the jet depends upon the head and since the velocity of the circumference must be one-half that of the jet it is necessary in some cases to build wheels of large diameter in order to bring the rotative speed within the required limit. An instance of this is the case of the plant recently installed for the North Star Mining Company, at Grass Valley California, which contains the largest Pelton wheel ever built. It is 18 feet 6 inches in diameter and is constructed somewhat like a bicycle wheel. Water conveyed through a pipe line five miles long is furnished under a head of 775 feet through a 1½-inch nozzle. The speed of the wheel, 110 revolutions per minute, is necessitated by the fact that it is directly connected to air compressors.

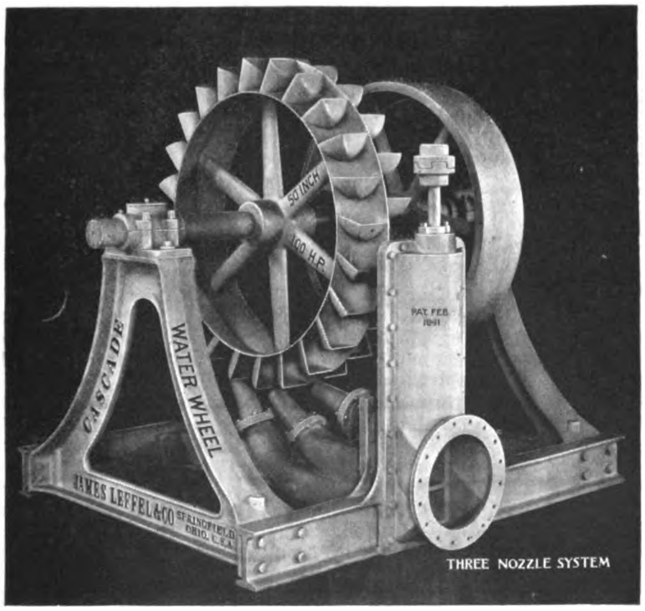

FIG. 10.—THE LEFFEL CASCADE WATER WHEEL.

Another form of tangential water wheel now on the market is known as the Leffel "Cascade" wheel, shown in Fig. 10. It differs from the Pelton principally in the design of the buckets. It will be seen that this wheel has two separate sets of buckets located alternately on opposite sides of a continuous dividing ridge. This dividing ridge has a sharp edge which serves to divide the jet of water before it reaches the buckets and keeps it divided into two equal portions, one portion being received by each set of buckets. It will be seen that the buckets are arranged alternately, or "staggered," with a view to obtaining greater steadiness of motion. The entire runner is cast in one piece making it at once strong and simple in construction, and preventing loosening of the buckets.

One of the greatest drawbacks to the use of water power has been, until rather recently, the difficulty of maintaining a constant speed under varying load. This has been especially the case where water wheels have been used to drive electric generators, an unvarying speed under all changes of load being in such a plant absolutely necessary. A variety of governors are now on the market, three of which may be described.

The Pelton differential governor, a general view of which is shown on the extreme left of Fig. 11, consists of four mitre gears, two of which are attached to pulleys which turn loosely on a shaft, the other two being capable of rotation about studs which project from a crosspiece rigidly attached to the same shaft. One of the pulleys is belted to the wheel shaft; the other is driven by a small motor in the opposite direction and at the speed which it is desired to maintain. As long as the speed of the wheel remains constant the gears on the crosspiece simply revolve on the studs, but as soon as the speed of the wheel changes, these two gears move bodily, rotating the cross piece and shaft to which it is attached. A pinion on the shaft moves a quadrant with which it is in gear and this operates a valve or moves the deflecting nozzle. Safety stops are provided to prevent the governor from acting when the valve is fully open or shut.

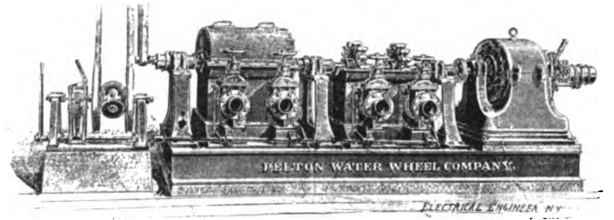

FIG. 11.—PELTON WATER WHEEL GOVERNOR.

The Replogle governor operates on an entirely different principle. Whenever a variation in speed occurs, an electric current is established, the current through this circuit energizing a magnet which attracts its armature, and thus actuates the mechanism for moving the gate. A small belt from the wheel passes over the small pulley seen in the upper part of the machine, Fig. 12. and by this means the governor balls are rotated. Any change in the speed of the wheel produces a change in the angular velocity of the balls thus raising or lowering the end of a horizontal rod, which touches one of two contact points and completes the circuit through one of two magnets. This magnet attracts its armature, thus throwing a piece in contact with a lug or a sliding table. This table is set in motion by means of a rod, actuated by a small crank on the shaft of the large pulley which is also belted to the water wheel. The sliding lug now forces one of two friction wheels into action and the gate is opened or closed as may be required. The speed governor will keep the circuit closed and the gate in motion until its speed is restored to normal, and might overdo the work, but for the action of a most ingenious device. The small pinion on the hand wheel shaft which gears with the quadrant, begins to rotate as soon as the position of the gate is altered. The consequent motion of the quadrant and quadrant shaft is transmitted to the two contact points by means of a cam on the quadrant shaft and the circuit is broken, thus preventing too great a movement of the gate. When the gate is either entirely opened or closed the electrical circuit is broken automatically and the governor prevented from further action. The manufacturers of this machine claim that it will regulate a water wheel to a given speed as closely as a Corliss engine.

VOL. XXIII. NEW YORK, MAY 26, 1897. No. 473.

THE SCOPE OF MUNICIPAL FUNCTIONS.

FOLLOWING out a practice in which it has indulged for some time past the New York Independent has had another discussion in its interesting pages, this latest being upon the public ownership question, presenting the views of a number of well-known men on the ownership of telegraphs, tramways, gas works, etc., and supplementing the longer articles by several "short testimonies" from various cities where municipal ownership has been tried. The articles are all good and well worth reading. If they do not settle the question, that need cause no great surprise.

The first contribution in the symposium is the excellent one of Dr. Albert Shaw, on the advantages of municipal ownership, but we have read it carefully without discovery of any new facts to justify the title. He appears to approve of the German civic method, of disregarding any underlying political principle and of settling each case on the point as to whether the proposed plant will pay. That seems to us treacherous ground for a teacher of public morality, but conceding its tenability, we must renew the expression of our deep seated doubt as to whether these plants in Germany or any other European country, or even in this country, "pay" in the rightful sense of that term. The assumption by Dr. Shaw that government in Europe has "dignity, character and strength," with the inference that here it has not, so that while they can handle affairs successfully over there we cannot, seems to us a little lacking in confirmation in view of the beautiful work of the Concert of the Powers in Eastern Europe and the awful, needless disaster in the Rue Jean-Gougon in Paris, both of which we take to be examples of absence of any kind of governmental skill, character or strength in dealing with a situation. Most government is bad everywhere, and people are best off when government handles least of their affairs, not alone in bureaucratic Europe but in the far commonwealths of Australia. Mr. William Epps, the secretary of the Australasian National League, in another of these articles, complains bitterly that this tendency to bureaucracy "has a most baneful effect on the national life of the people by making them look for everything to the State." In New South Wales to-day, one man in every ten is in the public service and "politicians approach with trepidation, or avoid, any scheme for retrenchment or greater economy, because their support would mark them out for opposition." We all know that such a statement is true. Some of us feel, therefore, that it should be one great aim to keep down the number of public officials, despite any plausible plea that it "pays." Mr. Epps in speaking of the State Railroads of Australasia mentions that a private road in New Zealand is running with working expenses of 46.13 per cent. of revenue, while the State lines take 63.51. The private line appears also to be the best worked and best equipped in the colony.

Among the other articles in this series is one by Prof. Edwin R. A. Seligman, in favor of the public ownership of telegraph and telephone; one by Prof. E. W. Bemis, in favor of municipal lighting, and one by Mr. Lee Meriwether, Missouri Commissioner of Labor, in favor of municipal street railways. According to Prof. Seligman, the United States and Canada lag behind in a primitive stage with telegraphs and telephones "used for purposes of extortion or profit," the later stages being trusteeship with tolls, government service run for profit, government service run only to make ends meet, and fifth and finally no charge at all. We confess our sheer inability to grasp the conditions of the last stage, where everything is to cost nothing, being defrayed by a general tax on the community. As a man would pay this tax whether he used the services or not, the extortion of the pirate barons of old was a form of benefaction compared with such rank, wholesale, unavoidable robbery of the citizen. A great many of the services in Europe operated by government are run at a loss now, and therefore the deficiency is made up by some such inequitable taxation. Moreover, they are run with terrible badness. In this country the postal service is conducted by the government, and we know of few things that could not be done better. There is not a big dry goods store or express company that in promptness and accuracy of delivery does not beat the postoffice clean out of its boots.

Prof. Bemis, of course, favors in his usual way municipal lighting plants, and offers as usual several propositions that do not hold. Having burnt his fingers over electric light statistics he lets them alone very carefully, but concludes that gas works are a good thing to spend public taxes on. When he explains satisfactorily why gas in Philadelphia, according to the last official report, takes three men to produce the same quantity that is produced by one man in private works, and when he explains also why the city is glad to buy its gas largely from a private company, we may be made ready to indorse his views as to the general desirability of such municipal enterprises. It would be strange, indeed, if there were no municipal enterprises well run; but Dr. Shaw intimates in his article that the municipality generally gets the poorest talent.

Mr. Meriwether's article is mainly a recital of his grievance that standing as a candidate for mayor in St. Louis, chiefly on a platform of confiscation, he got little support from the press, in his campaign against the street railway companies. He also rails at the average citizen for his low sense of duty and morality. The average citizen is all right, and it seems to be a good deal to his credit, anyhow, that there are some candidates for mayor that he turns down. Conceded that public franchises have a value, and should be paid for, it does not follow that the next step, of public ownership, is desirable. Even the value of the franchise depends not on its intrinsic merit as property, but on what the company can get out of it by energy and good service; and a high rate of franchise fee does not always inure to good service, as Mr. Higgins showed recently in his remarkably able paper printed in these pages. Prof. Laughlin, of the University of Chicago, meets the Meriwether arguments by his pithy point that transfer of ownership from private to public is not going to make the city official clean if he was corrupt before, and that "prudent arrangements with private companies may, by frequent renewals of franchises, produce nearly, if not all the gains of competition in low charges and efficient service." For ourselves, we believe rather in long franchises with frequent revision of terms as to rates chargeable, etc., but as to the whole question Prof. Laughlin seems absolutely correct when he says that the causes of municipal morality lie deeper than municipal ownership.

THE GAS ENGINE IN CENTRAL STATIONS.

THERE was a time when a bold writer might have undertaken to lay down the lines on which the central electric distributing station of the future would be laid out; but recent developments, it seems, have brought to light certain facts that may well cause the most sanguine speculator on the future of electrical generation to pause before venturing to express a positive opinion on that subject. For some time past not a few able engineers have expressed the belief that the steam engine would in time give way to the internal combustion or gas engine, and we are bound to confess that that opinion was shared by us, and for that matter is still unshaken, but one's faith gets a rude shock from some recent experiences recorded in England with stations in which gas engines have been used exclusively. To be specific, it seems that at Coatbridge, England, a station has after fifteen months' operation with gas engines, abandoned the latter in favor of steam. As this is a matter touching directly all stations now employing gas engines, and those contemplating their employment, it seems worth while to enter a little more deeply into the causes which have led to this radical step. The machinery of the Coatbridge station comprised three generating sets, each consisting of a 120-horse-power engine rope-geared to a 50-kilowatt Mordey alternator. The gas engines were double acting, two cylinder, side-by-side type, working on the Otto cycle at 185 revolutions per minute. The governing of the engines was by graded charge down to one-third of full power, below which explosions were missed. Each engine shaft carried three fly-wheels, and the system was arranged for the alternators to be run in parallel. Fuel gas was generated from anthracite coal, in generators resembling the Dowson type. We give these details in order that our readers may be familiar with the conditions existing in this particular installation. This plant was run from March, 1894, until the end of June, 1895, the load on the station being so small as to obviate the engines being run very often with the alternators in parallel. When the alternators were run in parallel, however, it is said that the result was not altogether satisfactory.

At the beginning of July, 1895, the gas plant was abandoned, and three vertical steam engines were installed in their stead. The results of the cost of operating the station during these two periods is illustrated in the accompanying table.

A COMPARISON OF COSTS OF WORKING OF COATBRIDGE ELECTRIC SUPPLY STATION RUNNING BY GAS POWER AND BY STEAM POWER.

——	1894	1895	1896
Period of steam-engine running	......	July to Dec.	Jan. to Dec.
Period of gas engine running....	April to Dec.	Jan. to June	......
Units generated.................	25,800	51,000	59,600
Cost of fuel.....................	£205	£305	£212 8s. 4d.
Cost of fuel per ton, for gas.....	18s.	18s.	......
Cost of fuel, per ton, for steam..	......	4s. 6d.	4s. 6d.
Cost of oil, waste, stores, etc.....	£130	£160	£84
Salaries and wages at station....	£375*	£482	£500
Salaries and wages at mains.....	£182	£142	£106
Net loss on year's working.......	£1,000 (9 months)	£,451	£663
Cost of fuel per unit generated.	2.545d.	1.435d.	0.855d.
Cost of oil, waste and stores per unit generated..............	1.25d.	0.753d.	0.338d.
Salaries end wages at station per unit generated...............	3.50d.*	2.27d.	2.03d.
Net loss per unit generated......	1.6d.	6.83d.	2.67d.

It will be noted that only nine months of gas engine work is given, but this is probably sufficient to enable a fair comparison to be made. It will be apparent also that the year of 1895 is a composite period, the first half representing gas practice and the latter half steam practice. Inasmuch, however, as it represents results of lighting intermediate between the other two sets of results, it tends to confirm the conclusion that the introduction of steam has effected an improvement in the financial results. In making comparisons between these figures it must not be overlooked that the output of the station was much lower in 1894 than in subsequent years, thus rendering the comparison unfair to gas. The managers believe on the other hand that not a little of the improvement in output of the station is due to the greater confidence consumers have acquired since it has been run by steam. Taking the figures as they stand, however, perhaps the most striking fact brought out in the table is that the gas engines cost much more for fuel than a steam plant. This apparently inexplicable condition is well accounted for by the fact that the anthracite coal required for the gas generators cost 18s. per ton, whereas the boilers are at present fed with local slack, costing 4s. 6d. per ton; and as a matter of fact in 1894 with gas, only 26.4 pound of coal was used per unit generated, whereas in 1896 with steam 35.3 pounds were required. It will thus be seen that the present steam plant which is working non-condensing, consumes nearly 33 per cent. more fuel than the abandoned gas engine. We may remark here, that if by the unit is meants as usual the Board of Trade unit, the kilowatt hour, the consumption of fuel in either case appears to us to be out of all proportion, indeed almost inexplicable considering the high class machinery employed.

The item next in importance to that of fuel, perhaps, is lubrication, which, it will be noted, amounted to 2½ cents per kilowatt hour, an apparently heavy indictment against the gas engine. This amount, it will be noted, includes, besides lubricating oil, the cost of ignition tubes and material for gas scrubbers. In 1895 no less than $5.10 per week was being paid for ignition tubes alone, four new tubes being used in each engine every day. The lubricating oil was not filtered nor used again, so that the expense on this score might have been reduced. Indeed, it is estimated that the best present gas engine practice would enable the cost of lubrication to be reduced to nearly one-third of that given in the above table. There are, however, other reasons which may have led to the resumption of steam in the Coatbridge station, which are not apparent from an inspection of the accompanying table. Among these may be irregularity of speed, imperfection of working at reduced loads, difficulty in starting, and noisiness. Our contemporary, the London "Electrician," to whose columns we are indebted for the facts above enumerated, remarks that the Coatbridge station is now a much less noisy station than it was during the gas engine days. Perhaps the most serious objection, however, to the gas engine arises from its behavior at light loads, for the fact remains, as proved by experience, that even governing by a graduated charge of fuel and air and working on the Otto cycle the consumption of fuel rises at an extremely rapid rate as the load falls off. On the other hand if miss-fire governing is employed, no regularity of speed can be maintained, at least for the requirements of electric lighting, and especially when alternators are run in parallel.

Besides the abandonment of gas engines at Coatbridge similar plants at Morecambe and at Belfast are shortly to be changed over to steam also. In Belfast, we may add as an extenuating circumstance, that the gas employed, although made from cheap bituminous coal, was obtained from the local gas company, who, of course, made a profit out of it before delivering it to the electric light company. We have thought it worth while to go into these details, as it bears directly upon a question of vital importance to central station managers. We must confess that, apparently damaging to the gas engine as the showing is, we are not prepared to consider the evidence presented as at all final or conclusive. The relative efficiencies of a gas and a steam engine are well known, and while we are aware that the mere item of fuel is not the only one to be considered in estimating the working efficiency of a plant, still the experience at Coatbridge is not one which we deem to be that of a truly typical case. But even admitting the defects as well established, are engineers to assume that the gas engine is incapable of improvements to meet the conditions imposed in electric central station work? We have full faith in the ability of gas engine manufacturers to overcome whatever difficulties may have been the cause of the dismal experience above noted. Of course, we may be confronted by the argument that gas engine building is by no means a new industry, and that it is to be fairly assumed that the gas engines installed at Coatbridge represented the best current practice; but even if such were the case, that would not alter the argument, since improvements are constantly being made even on the best standard apparatus of the day, and the gas engine has been the particular study of some of the best engineers of the day. It would be a matter of general interest to analyze the results of experiments in the United States with the operation of electric generators by gas engines, and we hope those who have had experience with them will come forward with the results they have obtained.

THE INSTITUTE.

THE election of Prof. Crocker to the presidency of the Institute is not only a well deserved recognition of long and disinterested service in its behalf, but an earnest of much good work to be done. Prof. Crocker has had the Institute handed over to him in excellent condition by Dr. Duncan, and has many excellent ideas for increasing its usefulness and enlarging its scope of effective action.

The "Wheeler" badge adopted at this annual meeting is an improvement on the old one in many respects, but in making the change the credit due to Mr. W. J. Hammer for his intelligent and enthusiastic work in this direction must not be forgotten or overlooked. The old badge embodying his ideas had many merits, and the fact that 400 were sold testifies to its popularity; but we think it will be generally agreed that the new badge is an improvement, perhaps chiefly because it is in line with those of the sister engineering societies. We understand that its beautiful and dignified design is due to a lady. If so, the Institute might recognize her work gracefully by presenting her with the first one jewelled, or in some such way testify its appreciation.

CHURCH SERVICE BY MACHINERY.

QUITE a dispute has arisen out in New Jersey over the use of the phonograph in church. One parson with a poor opinion of choirs has patronized the inoffensive machine and its little wax tubes, while another parson nearby thinks that if the phonograph is to sing the hymns, intone parts of the service and pronounce the benediction, it might as well preach his brother's sermon, too. So it might, provided the machine is all right. But there's the rub, as Hamlet said. A damage suit has just been decided against an electrical concern in this city because its organ motor installation gave out just at the thrilling moment when the choir was on its high C in the Easter Sunday musical performance, and left the melody of the soprano's "Ave Maria" swinging around helplessly in the church without a rudder. The choir came to a dead, sickening halt, the service was spoiled, the pastor lost his temper, the congregation felt gloomily for its hat and fan, and all the blithe and jocund sentiment of the glad Easter morn was sacrificed to the inefficiency of a poor machine. Such things ought not to be, and least of all in a church. Hence, if the whole service is to be run by a machine, the responsibility thrown upon the electrical contractor and the consulting engineer should be realized at its full weight in advance.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—XI.

APPLICATION OF STORAGE BATTERIES TO ISOLATED PLANTS.—Continued.

BY JOSEPH APPLETON. (Copyright, 1897.)

THE direct current system of electric lighting has been developed and brought to its present state of perfection in America by the Edison Illumnating Co., and the storage batteries are now playing an important part in the recent developments of this system.

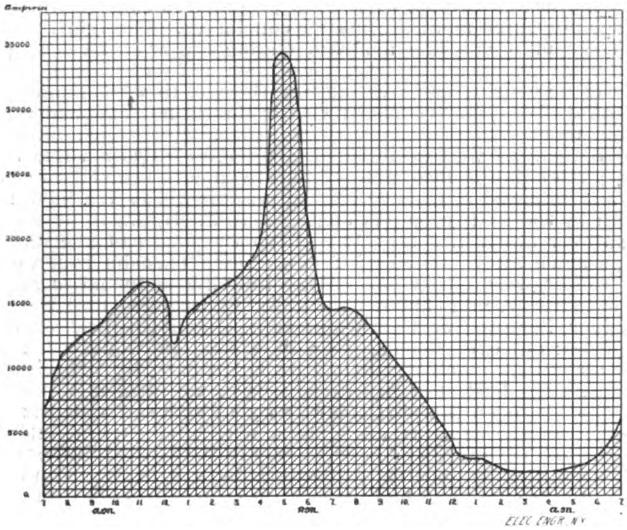

FIG. 37.—CENTRAL STATION LOAD DIAGRAM.

The method of distribution adopted by these companies is known as the three-wire system, which makes it possible to utilize direct currents over extended areas where the ordinary two-wire system would require such an investment in copper as to render it commercially impracticable.

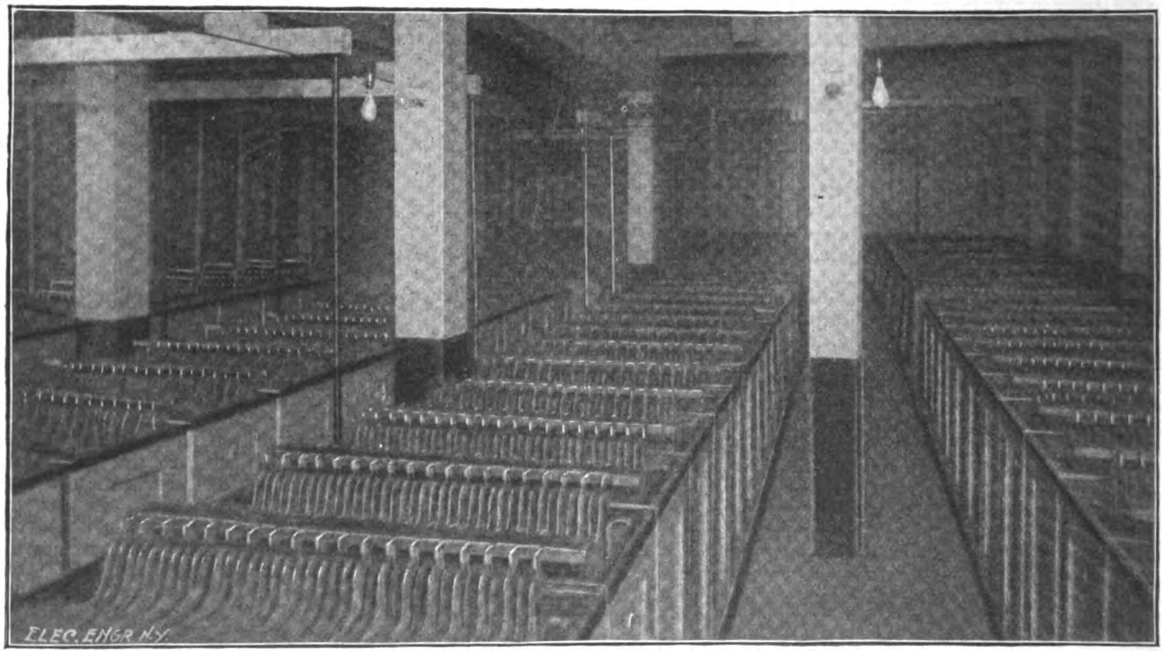

FIG. 38.—STORAGE BATTERY ROOM AT THIRD STATION OF THE BOSTON ELECTRIC ILLUMINATING CO.

The principle of this system is too well known to require explanation other than the diagrams given later. This same system is in general use in Europe, and it was there that the value of storage batteries in connection with it was first demonstrated, the Tudor Company of Germany being the pioneers in this field. There are now, however, to be found in America, storage battery equipments in connection with Edison stations which surpass European practice in both size and detail.

The various ways in which storage batteries can be used to advantage in central stations of this description may be divided into the following heads:

1. To carry a portion of the peak or maximum load which occurs for very short periods only, during each twenty-four hours.
2. To carry the minimum load, thus enabling the generating plant to be shut down during this period.
3. To equalize the pressure and maintain a constant load on the generating plant.
4. To act as a reserve in case of emergency.
5. For the equipment of sub-stations.

The local conditions in every case will determine which of the above will prove most profitable; examples of each application in actual practice will be described and illustrated later, but the following general explanation of the various methods will show the field which exists for storage batteries in central station work.

1. To Carry a Portion of the Peak or Maximum Load.—In central stations supplying current for lighting purposes, the load curve, especially during the winter months, takes the form of a peak for two or three hours during each day, see Fig. 37, at which time the load is generally double that at any other in the twenty-four hours. This means that sufficient generating plant has to be installed to carry the maximum load, while only about 50 per cent. of it is used for more than two or three hours per day; the remainder of the time it lies idle and unprofitable.

Various attempts have been made to straighten out the load curve, making the maximum load less of a peak and more of a gradual rise, but the very nature of the demand for light makes this impossible. The practice of supplying current for motors will increase the average load during the twenty-four hours, but does not get rid of the peak. One of the largest Edison Illuminating companies has found that dividing their maximum load during the year into two parts, the upper half consists entirely of peaks, containing only 10 per cent. of the total output, the lower half being 90 per cent. The value of a storage battery under these conditions is obvious.

2. To Carry the Minimum Load.—It will be seen from Fig. 37 that there are several hours during the twenty-four when the demand for current is very light, and the cost of production per kilowatt hour is much greater than at any other time. In many cases a great saving in fuel and operating expenses can be effected by shutting down the generating machinery during this period and carrying the entire load on the storage battery, which has been charged at a time when the generating machinery was operated under more economical conditions and therefore producing current at a cheaper rate.

3. To Equalize the Pressure and Maintain a Constant Load

on the Generating Machinery.—The use of a storage battery for this purpose appeals at once to those connected with the operation of central stations. As the use of electric light becomes more general, it is all the more necessary that the supply be steady and regular. Again the demand for current for motor and elevator service is rapidly increasing and this being an extremely fluctuating load causes unsteadiness in the lighting service, so much so, in fact, that central station managers are often compelled to refuse this class of work on account of its disturbing influence unless a storage battery is used to equalize the pressure.

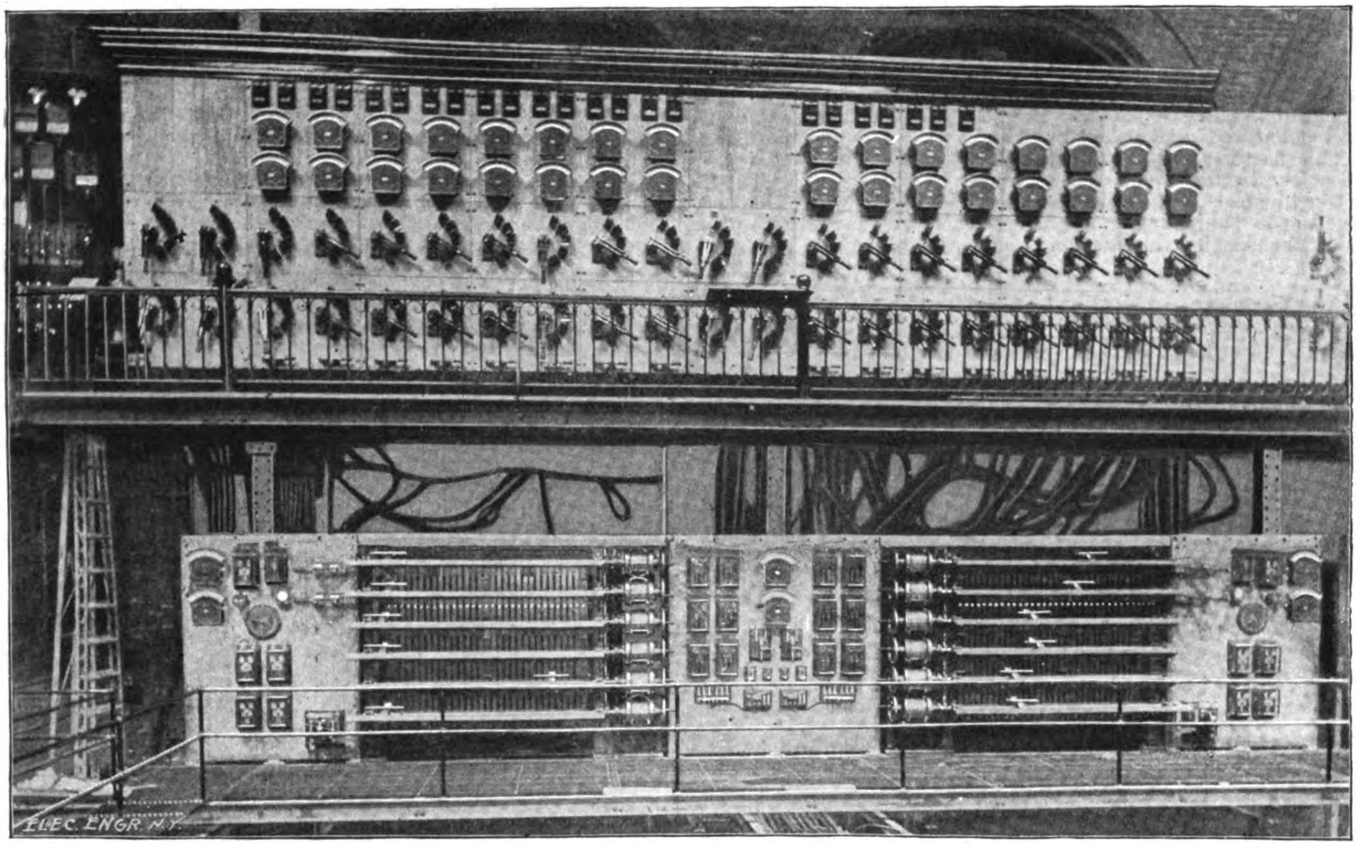

FIG. 39.—STORAGE BATTERY SWITCHBOARD, THIRD STATION, BOSTON EDISON ELECTRIC ILLUMINATING CO.

The advantage of maintaining a constant load on the generating machinery is evident, as it is the ideal condition for economical operation.

A storage battery enables this to be done to a much greater extent than by any other method; it allows of larger units being used, and keeps those units fully loaded, the surplus current being stored up in the battery and any demand in excess of the capacity of the generating plant being taken care of by the battery.

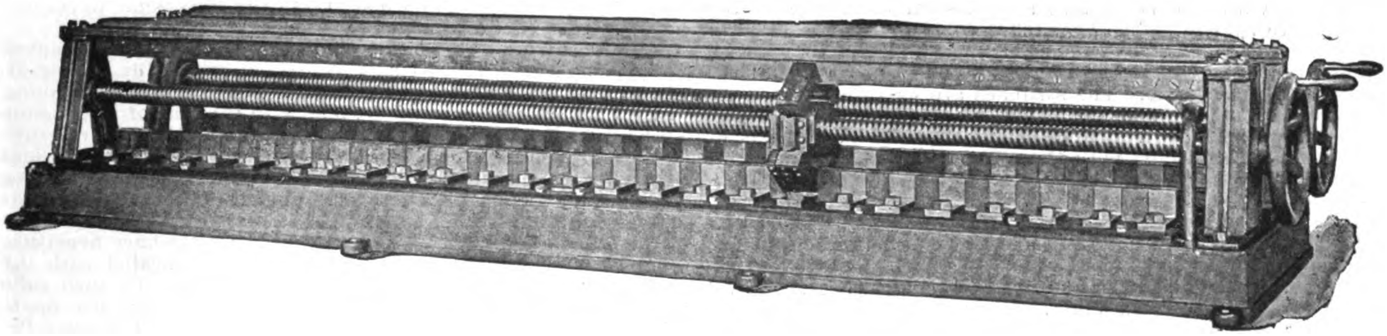

FIG. 40.—END CELL REGULATING SWITCHES FOR CENTRAL STATIONS.

It is impossible to overestimate the value of a storage battery for these purposes, as the advantages derived are so numerous that they cannot be reckoned in dollars and cents.

4. To Act as a Reservoir in Case of Emergency.—The question of reliability of service is of the utmost importance, and any method whereby this is increased cannot be too highly valued. Only those actually connected with the operation of central stations know the anxiety and worry attached to this work, and therefore, they alone can fully appreciate the security and value of a storage battery having sufficient capacity to tide over any short periods of mishap which are liable to occur in any plant, or any sudden increase of load due to weather changes, etc.

5. For the Equipment of Sub-stations.—This application of the storage battery is one of recent developments of the direct current system of distribution, and is most useful in the case of large cities where the suburbs and residential districts are too far from the main generating stations to be supplied economically during the hours of maximum load. By means of suitable battery sub-stations the center of distribution for these outlying districts can be located where it would be impossible to erect a generating station, and moreover, can be operated with much less expense.

The battery is charged from the main generating station when the load is light and the loss over the feeders or lines is small, thus securing the advantages of loading the generating machinery when it would otherwise be idle and relieving the distributing system of conductors of a portion of the current which it would otherwise have to transmit at times of maximum load. This system also enables a motor or elevator load to be carried in the outlying districts which would be extremely difficult, or perhaps impossible with the ordinary three wire system. We will now consider some of the instances where the above mentioned applications have been put into practical operation.

The Boston Edison Illuminating Company was the first electric light company in America to adopt storage batteries to any extent. They have three equipments in actual operation, and are now installing a fourth. Their first storage battery consists of 140 cells of the Tudor type, installed on the three-wire system, giving them a capacity of 3,300 amperes for one and one-quarter hours 1,716 amperes for three hours, 694 amperes for ten hours.

This battery is installed at their Third Station, which is the main generating station, being equipped entirely with modern apparatus, triple expansion engines, all condensing, and direct connected multipolar dynamos.

This battery plant is illustrated in Figs. 38 and 39, which show the battery room and switchboard, respectively. In the latter illustration the lower portion is the battery switchboard, the upper board being a part of their regular distributing switchboard. In this station there are five sets of busses to give different pressures as required; therefore, the battery is provided with five regulating switches on each side of the three-wire system. These switches consist of 31 contacts to which are connected 30 of the cells on each side of the system, thus allowing any number of cells, from 40 to 70, to be connected to the system. The switches are operated by motors controlled from the distributing switchboard.

Fig. 40 illustrates a switch of this type, which consists of the contacts connected with the respective cells, a continuous copper bar, connected with the buss, and a sliding brush traveling on a quick thread screw which makes connections between the contacts and bus bar. The traveling brush has divided contacts, with a resistance inserted between them as previously illustrated and described (Fig. 27), to prevent opening the circuit or short circuiting the cells during its travel from one contact to the other.

"THE BEST PUBLISHED."

Mr. H. F. Cottle, chief of the Electrical Construction Division of the city of Boston Public Buildings Department, writes us: "Please find enclosed subscription for the coming year from May 19. Regarding your paper, I wish to say that I believe it is the best electrical journal published, and one that I always advise my friends to get, for the reason that everything in it is easily understood and in such language that the practical man can grasp the sense of the subject."

GENERAL ELECTRIC REVOLVING FIELD ALTERNATING GENERATORS.

Among the latest additions to the apparatus manufactured by the General Electric Co., is a new alternating dynamo of the so-called "inductor" type, in which the field revolves and the armature is stationary.

This machine, which is illustrated in the accompanying engraving, Fig. 1, has been designed especially for very high and very low voltages, and possesses a number of interesting and valuable features. The chief among these are the following: The wire on the armature, being stationary, can be effectively insulated for high pressures, and the machine can thus feed directly into the line without the use of step-up transformers.

The only collector rings on the machine are the two used for conveying the exciting current to the revolving field coils. They are therefore small affairs, subjected to a low potential, and their brushes can be handled while the machine is running without danger. All the high potential terminals are thoroughly insulated, and it is practically impossible to receive a dangerous shock from the machine.

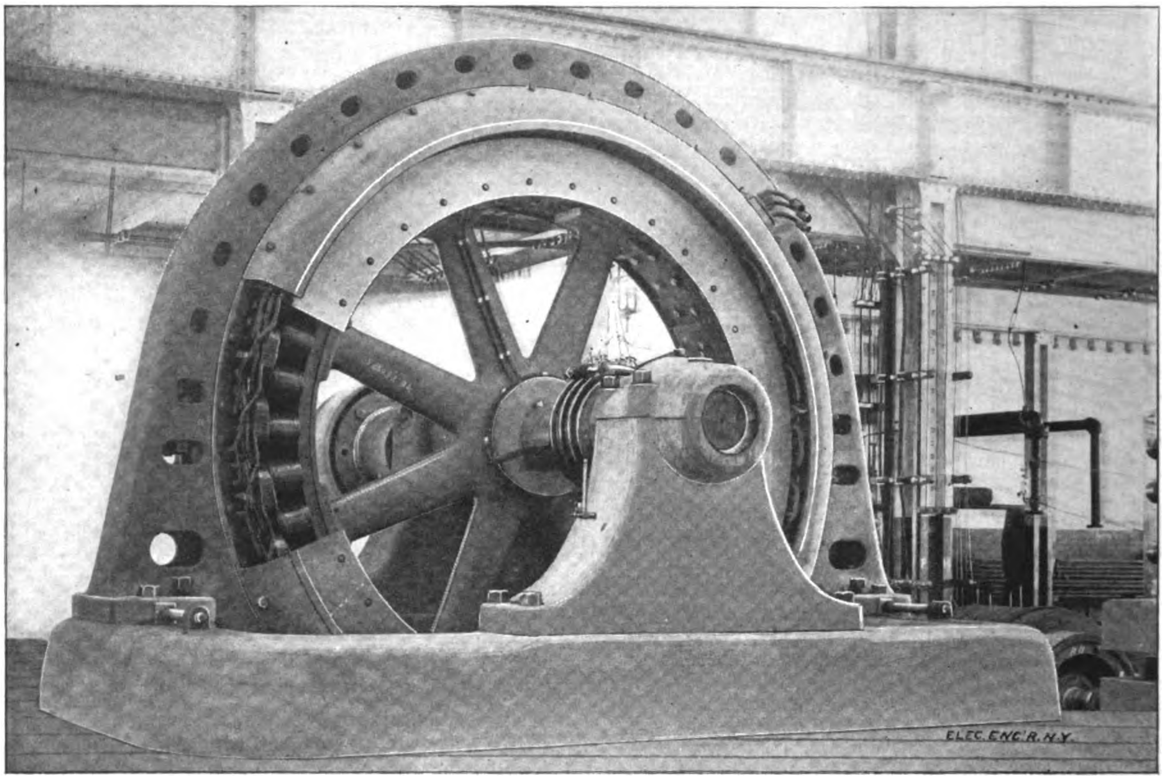

Fig. 1.—New General Electric Revolving Field Alternator.

The revolving field is very substantial, and has laminated pole-pieces, which are easily detachable. The engraving illustrates a 40-pole, 750 kilowatt, three-phase generator running at 175 revolutions per minute, and with sections of the shields removed, shows the arrangement of the field and armature coils very plainly. On the large sizes of this type the field coils are wound with copper strip placed on edge, thus forming single helices and giving a maximum radiation for the heat developed in the coil.

The machine is so constructed that the stationary armature can be moved along the base in a direction parallel with the axis of the revolving field shaft, thus exposing its own coils and those of the field for repair. These machines are made for various voltages, speeds and periodicities, and monocyclic, two-phase or three-phase, as conditions may require.

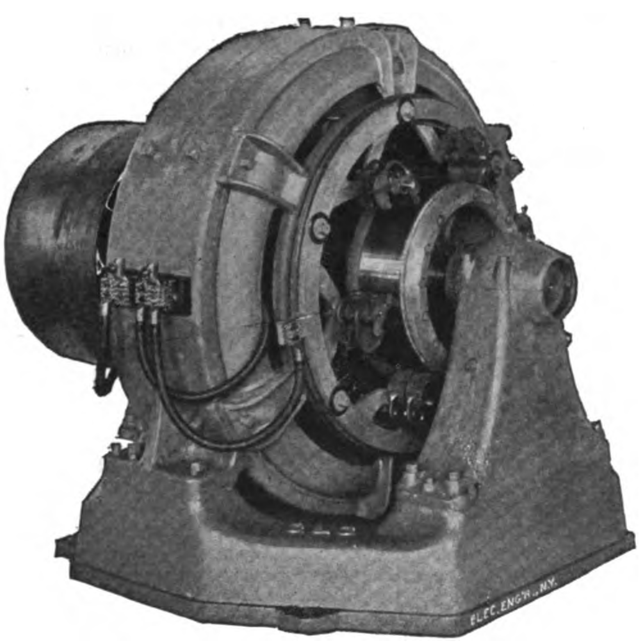
LIGHT WITHOUT LAMPS.

The best proof of the intelligence, the good taste of a theatrical audience is its conduct during an accident on the stage. In a German theatre in this city the other night a real mishap did not cause any unseemly demonstration. The heroine told a servant to bring in a lamp. Without waiting a moment the electrician in the wings turned on the light full power. About five seconds later the maid appeared at the door bearing the lamp, a palpable and ludicrous case of effect preceding cause, of putting the cart before the horse, in fact, what Dr. Trench would have called a preposterous business. Of course, it is possible that this German audience did not have a keen sense of the ridiculous.—N. Y. Sun.

THE DESIGN OF THE NEW C & C DIRECT CONNECTED DYNAMO.

BY D. W. BARNES.

PLACING a new direct connected or slow speed dynamo on the market in 1897 is a different matter from what it was a few years ago. At that time almost any dynamo could be sold, but to-day the specifications of the consulting engineer and architect pretty closely define the type of dynamo which will be accepted by them, and that type which has for its field piece a ring with radial poles projecting inward encompassing an armature with its winding buried in slots has come to be practically specified. They even go further and specify the detailed construction of the armature and say that the armature and commutator shall form a single unit so built up on a sleeve as to permit of readily assembling on the engine shaft. They name the material of which the commutator bars shall be composed, and will have nothing but carbon brushes. They state the efficiency, heating limit, current density in brushes, regulation required and what material shall be used for insulation. They dispose of the question of brush movement by stating that there shall be none at all. We expect they will soon state the weight of the machine. All this is good for the honest manufacturer. It shuts out inferior competition, and in spite of the severe conditions the field is far more attractive than before; there is a possibility of reward for merit. Price alone is not the basis of awarding contracts for this class of dynamo electrical machinery.



THE NEW C. & C. SIX-POLE GENERATOR.

The consulting engineer and architect having therefore settled the general design it remains for the manufacturer to work out the details of the problem. After all it is the working out of the details that determines success or failure, and it is only with the aid of that engineering judgment that comes from experience that the best results are obtained. No set formula can produce a good dynamo any more than it can a good steam engine, and yet without the formula we could not begin. It is possible to design so that the dynamo will have a high efficiency at all loads, which is better than a high efficiency at full load and a low efficiency at one-half load. Every practical engineer knows that a dynamo under average conditions is not fully loaded.

The net commercial efficiency of the C. & C. six-pole direct connected dynamo, which is a recent example of new and careful design, is 92 or 93 per cent. at full load, in the larger sizes, and careful tests show a falling off of only 3½ per cent. at one-half load. An efficiency curve taken from a 60-kilowatt C. & C. direct connected generator showed a net commercial efficiency of 80 per cent. at ¼ load.

The reader may be interested to know how the design of this dynamo was worked out. In the first place it was decided that there should be no skimping of material, either in quantity or quality, to secure low cost. All attempts at economy in construction were therefore directed toward the labor side of the problem. On this account, while the electrical designers were given free rein to produce the highest efficiency, the mechanical designers applied as careful study to the problem as they would to the construction of a steam engine, reducing the number and expense of the operations wherever possible without reducing the quality of the workmanship. There was no haste in the designing; ample time was given to study the "machine problem." The result was highly creditable from a mechanical standpoint; the new dynamo proved to be a handsome machine, which the writer claims is an indication of good design. A machine that properly combines simplicity and strength pleases the eye.

The armature coils are form-wound, the slots being separately insulated with fireproof insulation. The field coils are reinforced for protection, and are interchangeable. The air gap is sufficiently small to avoid the necessity of large magnetizing currents, and the flux densities determined with a special view to sparkless commutation. In this respect the results are very flattering. The 60-kilowatt machine already mentioned, was loaded up to 75 kilowatts and ran several hours at that load with practically no sparking, and without shifting the brushes. Our friends, the consulting engineer and architect, having frequently specified that machines shall carry an overload of 25 per cent. have disposed of the question of sparking, since a dynamo that is inside the sparking limit at 25 per cent. overload will certainly be so at normal load, or under average running conditions.

It has been stated that people frequently do not recognize facts until they come into violent collision with them, but the fact regarding direct connected dynamo design of to-day is that only a high grade machine like the one described can fill the requirements of the market, which are more exacting than ever, and which tend to make dynamos of American manufacture the best in the world.

MUNICIPAL LIGHTING MUDDLE AT MIDDLEBORO, MASS.

The municipal lighting of Middleboro, Mass., has now reached another deadlock, and the town is likely to be in darkness unless some steps are taken immediately to straighten out the matter. The town got discouraged recently over the costly maintenance of the plant, and a special investigating committee consisting of Dr. E. S. Hathaway and John A. Miller was appointed. After going into the matter carefully they reported to a town meeting recommending many decided changes in the running of the department, and also a reduction in the number of arc lights, substituting incandescents for the arcs dispensed with. At present they have about 100 arcs and they propose to change these to 25 arcs and a proper number of incandescents. Their recommendations were adopted.

A few weeks ago the Hon. N. F. Ryder, who is a member of Governor Wolcott's executive council, resigned from the Lighting Board, and Commissioner J. B. Ryder, who is also manager of the lighting plant, called a halt, as the recommendations and changes made by the special committee could not be carried out for the amount stated in the estimates they submitted. Mr. C. Sparrow did not agree with Mr. Ryder, and promptly resigned from the Board of Commissioners.

What legal complications, if any, may arise, no one can tell. In the meantime, as the manager, Mr. Ryder, is the only commissioner left in office, the prospect is that the lights will go out, he being unable to draw funds from the city treasury to pay the current bills, as the checks require the signatures of at least two commissioners. Such a state of things could hardly exist if the plant were operated by a private corporation.

WHAT A CITY PLANT IS.

The Cumberland (Md.) Times volunteers the following definition: A city electric light plant will only be another handle to the political pump for politicians to work.

MANHATTAN ELEVATED.—It is now stated that the New York Elevated will not adopt electricity until further developed and perfected! The company is worse off for courage even than for money. Waiting for the perfection of electricity is too funny.

LETTERS TO THE EDITOR

RANKINE AND WEISBACH AS AUTHORITIES ON HYDRAULICS.

YOUR issue of May 12 contains an article by W. E. Wines on "The Principles and Construction of Water Wheels," in which the following words are used:

"It has been overlooked by such authorities as Weisbach and Rankine, who insist that the velocity of the wheel-vanes and jet should be equal, to avoid what they call shock, but which in reality causes the loss of the impulse action of the water. The honor of correcting this error and building turbines which utilized both the impulsive and reactive effects of the water, belongs to two Americans, Uriah A. Boyden and James B. Francis, whose improvements have been universally accepted and followed, at least in this country."

The undersigned has no doubt but that every professional reader of the article has had the same experience as the undersigned had, when reading the quoted lines. I had to re-read them twice to arrive at the conclusion that my eyes did not deceive me, that there was, in fact, in existence a writer on matters of hydraulics, who possessed sufficient temerity to accuse the two greatest mechanicians of the century of ignoring the very first rudiment in hydraulics.

Both Weisbach's and Rankine's works contain pages and pages on the true conditions on which the absorption by a power wheel of the force evolved by weight and motion of water ejected under head or pressure rests. It is not true that these authorities overlooked that both the impulse and reaction have to be beneficiated for the purpose of securing highest efficiency, nor has either of the two ever claimed that the said force could be at all absorbed, when the circumferential velocity of the wheel and the velocity of the ejected liquid or fluid mass is equal. Nobody can claim an honor in presuming to correct an error which was never committed.

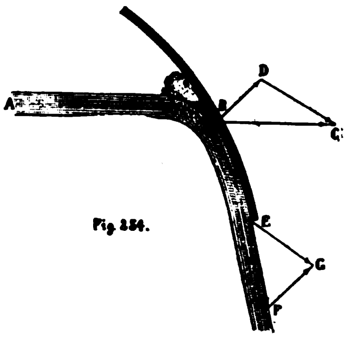


Fig 254.

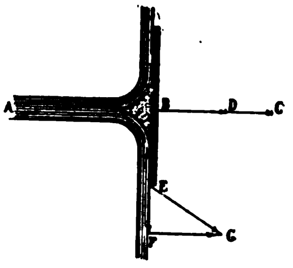

Fig 255.

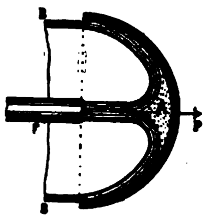

Fig 256.

I quote below the two authorities whom your contributor has tried to put to shame, in their own words, in order to show conclusions on their part, which could never have been arrived at by them had they not taken the precisely adverse position assigned to them by Mr. Wines.

The quotations alluded to read as follows:

W. J. M. Rankine, Professor of Civil Engineering and Mechanics in the University of Glasgow, asserts: (p. 594, 14th Ed. London, 1895.)

"If $B = 90^\circ$, as in Fig. 255, the maximum energy transmitted is $e. Q. v^2 \div 4. g.$ or half the original actual energy of the fluid. If $B = 180^\circ$, as in Fig. 256, the maximum energy transmitted is $e\ Q.\ v^2 \div 2\ g$, or the whole of the original actual energy of the fluid, which, after the collision, is left at rest."

Dr. Phil. Julius Weisbach states on page iii., § 24, Am. Ed.: "The water produces its maximum mechanical effect, when $v = \frac{c}{2}$, or when the surface struck moves in the direction of the stream with half the velocity of the stream. The maximum work is then

$$Pv = (1 - \cos. a)\ \tfrac{1}{2} . \frac{c^2}{2g} . Q = (1 - \cos. a)\ \tfrac{1}{2}\ Qh.$$

Now, if $a = 180^\circ$ — i. e., if the motion of the water is reversed by the impact, we have for the work done, $2 . \frac{1}{2} Qh = Qhy$; but if $a = 90^\circ$ — i. e., if the stream strikes against a plane surface—the work done is only $\frac{1}{2} Qh$, and the water transmits to the surface only one-half of its actual energy, or but one-half of the mechanical effect corresponding to its vis viva."

If it is honor to carry out in practice, what great men have laid out in theory, then this honor belongs to the American Impulse Wheel Company of New York, manufacturing a water wheel, the vanes of which precisely perform, and perform precisely in all their positions while revolving, the inversion of direction of flow for the liquid or fluid current that impinges the wheel, as was well illustrated by the article descriptive of that wheel published in The Electrical Engineer of April 14, 1897, page 413.

No other wheel ever offered for use, whether it be a submerged turbine or a free jet impulse wheel has complied or does comply with the theoretical conditions to highest efficiency, as the wheel of the above company does.

New York.

THE UNSETTLED BERLINER CASE.

My opinion, personally, having been asked upon the recent decision of the Supreme Court, I beg to state, briefly: The Supreme Court decision in the Berliner patent case was a victory for the people and a defeat for the Bell Company. There were four points of contention, any of which might have been a defeat for the Bell Company, in case of favorable action. Upon these three points the Bell attorneys fought with all their vigor against adjudication, indicating their absolute fear of the result. If they had had confidence in it, they would have brought an adjudication upon all of them. If they had had confidence in any one of them, they would have endeavored to take advantage of it by getting a favorable decision. Their whole effort was to prevent a decision upon any other point than that of alleging fraud upon their part in delaying the issue of the patent. They gained upon this point, but lost upon the three others, for there is hardly a doubt that they could have had an adjudication by the Court of Appeals upon the other points, if they had not fought it so severely.

Therefore, their fears are substantiated by facts, and, taken all in all, the farcical litigation between the Bell people and the Government, is, in fact, a victory for the people.

J. E. KEELYN, President.
West. Telephone Cons. Co.

Chicago, Ill., May 17, 1897.

THREE MOTORCYCLE INVENTIONS.

As an evidence of the attention inventors are giving to motorcycle transportation methods, it may be noted that the U. S. Patent Office has granted patents this week on three widely differing modes of travel. These include a marine velocipede, a motor-driven sleigh and wings for aerial flight.

WOMEN "ELECTRICAL WORKERS."

"Cleveland, O., has a large number of ladies who are connected with the electrical business, and who are first-rate manipulators of electricity," says Business Agent Connelly. "The electrical workers have a strong union, but in its formation they overlooked the women. It is now proposed by the Electrical Workers' Union to request the ladies to come in with them. It may be necessary to form a separate union. The matter has been broached to the women, and they are heartily in favor of it. An effort will be made to get them together and instruct them in the principles of unionism. With both male and female electrical workers organized, the people of that trade would be invincible."

TELEPHONY AND TELEGRAPHY

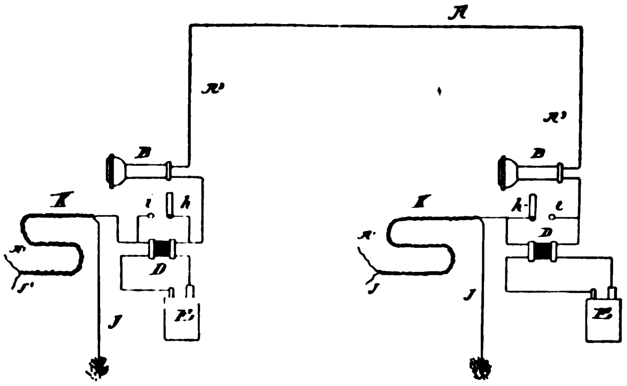
THE ABSTERDAM SYSTEM OF "MAGNETIC" TELEPHONY.

SOME time since Mr. John Absterdam, of this city, brought out a system of telephony in which the line is claimed to be discontinous, in order to demonstrate that a continuously closed circuit was not necessary to the transmission of articulate speech. In this system, it may be recalled, Mr. Absterdam employed at each end of the line coils wound with two conductors, side by side; but the opposite ends of the conductors connected to the receiver and to the line, respectively, were left open ended, as shown in the accompanying diagram.

Recently Mr. Absterdam has been at work on another part of the problem of telephony, which has resulted in what he terms a method of transmitting speech "magnetically."

The accompanying diagram illustrates the arrangement adopted for this purpose. A represents a single conductor extending from a telephone station A^2 to a second telephone station A^3 and including at each end a telephonic instrument B. At each station there is an induction coil D and a local battery E, the poles of which are connected in circuit with the primary wire of the adjacent induction coil, so that the battery current flows continuously and uniformly through the primary wire of the induction coil.

At each station the secondary wire of the induction coil is connected into the main line A. The respective ends A' of the main line A instead of being grounded or otherwise connected are terminated at each station adjacent to a wire J, one end of which is grounded. The ends of the wires A' and J' may be twisted together into a cord, K, and are insulated from each other, thus leaving the line A open at both ends, as shown at A' A', so that it is impossible to pass a current directly over the line or to operate telegraph instruments, bells, or analogous instruments thereon.



ABSTERDAM'S SYSTEM OF "MAGNETIC" TELEPHONY.

Mr. Absterdam extends the cord formed by the wires A' and J' into a coil of a considerable length, taking care at all times to maintain a perfect insulation between them, so that they shall not form in any sense or possess any of the peculiarities of condensers, according to his idea.

In practice he finds that although the line may be open at both ends, as above described, and although there may be no battery current upon the line and no interruption or pulsation of the primary current through the induction coils, as is generally believed to be necessary to set up secondary or induced currents in the line, nevertheless there exist in the line conditions such that articulate speech or other sounds uttered at a telephone at either station will be heard and understood in the receiving telephone at the other station.

As will be seen, the general arrangement of apparatus somewhat resembles that of an ordinary telephone line in that an induction coil, local battery, and telephone receiver or transmitter are used, but differs essentially therefrom in that the local battery is not used to set up the speech vibrations or variations, but the local current is allowed to flow without interference from any transmitting devices upon the local circuit which maintains the magnetic field in inductive proximity to the line, while the magnetic variations corresponding to speech are originated at some other portions of the circuits or apparatus independently of the local.

A CALL FOR AN INDEPENDENT TELEPHONE CONVENTION.

PRESIDENT J. E. KEELYN, of the Western Telephone Construction Co., Chicago, has issued, under date of May 18, the following call:

The action of the Supreme Court upon the Berliner patent has been so erroneously published, that the people, generally, have been seriously shaken in their confidence in the Independent Telephone movement. It is a satisfaction to know that there is little or no loss of confidence among the best informed of our telephone exchange people. We have been flooded with telegrams from all directions asking what effect the Supreme Court decision upon this Berliner patent would have. Most of these telegrams came from people whom we have little or nothing to do with and to whom we are under no obligations. They, undoubtedly, could get no information from the sources they had relied upon, as these very sources were in the foremost ranks of those to apply to us.

The very first people to call upon us for help and information were so-called manufacturers who heretofore have shown a spiteful jealousy of our success. In order to set this matter clearly before the public—in order to bring harmony out of chaos, and to strengthen the general business—a meeting was held at the office of the writer yesterday and he was advised to call a general meeting of all the Independent Telephone Exchanges in the United States to be held in the city of Chicago, Thursday, Friday and Saturday, May 27, 28 and 29. This is a short time in which to give notice, but prompt action is desired.

The Bell Company, undoubtedly, will bring action on this Berliner patent, therefore a united policy will be beneficial. The envious and jealous bickerings between other manufacturers, because of our success in these matters, have led us to believe that there is little to hope for from them in any combination of interests. They are always anxious to get all the benefit, but unwilling to make any expenditures for it. The ingratitude, and spiteful disposition of some of those mostly benefited by our victories in the Watson, Roosevelt, and other patent cases, has concluded us to refuse the use of our legal information on this Berliner patent, excepting to our friends. We are absolutely certain of our ability to defeat the Berliner patent, if a suit is brought against us or our guaranteed customers. We do not propose to be small about it, and shall, as in the past, extend a sheltering wing to all those who are kindly disposed. We positively will not be a party to any arrangements with a certain set of envious and jealous manufacturing concerns, who, for nearly a year past, have been in an underhand combination to fight us, but who were among the very first to beg us for help, notwithstanding that they represent themselves as being the "largest manufacturers," etc., when, as a matter of fact, their ability to defend a customer in court amounts to nothing.

The writer has therefore thought it best that the operating exchanges should get together in representative form and determine upon a proper policy to follow, and act in unison, and create an organization of a national character which will tend to the mutual advantage of all, not only upon this Berliner patent question, but upon all general matters affecting the Independent Telephone Companies.

This call is not to be misconstrued as a call for financial assistance. Our company has never asked it, and never will, as it is the duty of the manufacturer to provide the defenses and the means in accordance with his guarantee.

BELL TELEPHONE STOCK AND ITS HOLDERS.

There are 213 sheets of foolscap paper in the statement of the stockholders of the American Bell Telephone Company, says the Boston Journal. There are 236,500 shares of stock with about 6,600 different stockholders in the company. Last year it required 190 pages, showing there were then about 5,400 stockholders, which shows that there has been an increase during the year of about 1,200 stockholders.

Last year Mr. William H. Forbes was the largest stockholder with 3,329 shares to his credit, but he has decreased his holdings to 1,742 shares, and this year Mr. Theodore N. Vail, who has held no stock during the past four years, appears as the largest stockholder with 4,805 shares. The thirteen directors this year hold 5,651 shares of the stock, compared with

7,770 shares last year. Of the thirteen directors, five, whose holdings have been the largest, have decreased, five show no change, while three show a combined increase of 237 shares.

The fact that the name of Mr. Vail appears upon the stockholders' list of the American Bell Telephone Company this year as the largest holder of the stock causes considerable surprise and much surmising. Mr. Vail was formerly general manager of the American Bell Telephone Company, and since his retirement it has been understood in Boston that he has not been in a financial position to become, as he has, the largest stockholder of the Bell Company, with 4,804 shares to his credit. At $235 per share this stock has a value of $1,128,940, and at the present rate of dividends, $15 a year, the stock receives $72,060 annually in dividends. It is alleged that Mr. Vail, who lives in New York, has been closely identified with the Western Union Telegraph Company, and that he is especially intimate with President Thos. T. Eckert. This gives the impression in some quarters that the Western Union Telegraph Company has been buying Bell Telephone stock through Mr. Vail.

THE TELEGRAPH CONCESSION IN VENEZUELA.

According to the Venezuelan Herald of May 8, the concessions for the working of the government's telegraph system, which were granted to J. Schwed of this city, have been rejected by the Venezuelan Congress. The Herald says that when Mr. Schwed obtained the concession he arranged for a deposit with the United States Legation on April 13 of $25,000. It also says that Mr. Schwed went to Caracas as the representative of Henry Clews & Co. When April 13 passed and the deposit was not made, according to the Herald, the government withdrew the concession.

When asked about this matter last week a representative of Henry Clews & Co. said: "The report in the Herald is incorrect in several particulars. Mr. Schwed did not go to Venezuela as our representative. He is an employé of this company and has desk room in our office, but before going to South America he left on a vacation. He went over to Germany, and there organized a company or syndicate to operate the telegraph lines of the Venezuelan government. Upon submitting his proposition to that government it was accepted, and a concession for working the lines for thirty years was granted to him. The capital was arranged for in Europe, and Mr. Schwed is well able to carry out his part of the contract.

"So far as we know, there is no truth in the statement about a deposit being required. We have seen Mr. Schwed's contract, and no deposit is mentioned. He was allowed, moreover, six months in which to take charge of the lines, and should now have a margin of nearly five months.

"Instead of a deposit being demanded of him, the Venezuelan government contracted to pay him a subsidy of $150,000 a year for transmitting its messages. Mr. Schwed is ready to comply with all the terms and conditions of his contract. We wish it understood, however, that he does not represent us in this matter, but is acting for himself and for the German capitalists with whom he has made arrangements."

THE GOVERNMENT AND RAPID TELEGRAPHY.

Senator Pettigrew has introduced a bill in the U. S. Senate authorizing the Postmaster General to acquire for the United States the invention of Prof. Crehore and Lieut. Squier for rapid telegraphing by alternating currents, and also to construct a line between Washington and New York for the purpose of experimenting with and perfecting the use of rapid telegraphy.

THE POLES of the telegraph lines in Europe are said to have cost $50,000,000. The basis of this curious estimate is not given.

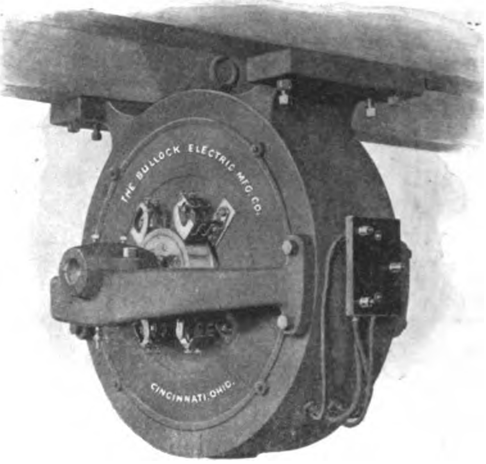
ROCHESTER, N. Y.—The Bell Telephone Company is trying to shake out the deadheads, and has issued positive orders that only subscribers are to be allowed to use its telephone service. The statement is made that out of 10,000 calls in a day, the company found lately that 4,000 were by persons whose voices were unknown as those of regular users entitled to the service.

SAN FRANCISCO, CAL. The John L. Klein Electrical Works have been formed at San Francisco with a capital stock of $50,000, subscribed $2,700. The object is to make and sell electrical supplies. The directors are J. M. Klein, San Rafael; C. W. Nevin, H. A. Sayles, J. Stone and J. W. Felt, of San Francisco.

POWER TRANSMISSION

NEW BULLOCK MOTORS.

THE advantages of the new types of direct connected line shaft and ceiling motors recently put on the market by the Bullock Electric Manufacturing Company, of Cincinnati, O., which was formerly known as the Card Electric Motor and Dynamo Company, of the same city, are becoming very generally recognized. It will be remembered that this company has always made a specialty of equipping printing establishments and machine shops with motors directly attached to the presses or tools. They are now enlarging the scope of the field of motor application by providing each counter shaft or line shaft with slow speed direct connected motors, which run at the same speed as the shafts, and are connected to them by special jaw couplings. It has long been recognized by mechanical engineers that the transmission of power by means of vertical shafting or belting has been a source of wastefulness; besides rendering the establishment liable to breakdowns which might seriously affect the output of the factory. The electrical engineer has now come to their assistance by supplying the only correct medium of transmitting power throughout a factory with the smallest loss of energy in so doing.



THE NEW BULLOCK CEILING MOTOR.

The motor herein illustrated shows the type, and particular attention is called to the compactness, strength and correct mechanical design, combined with high electrical efficiency and simplicity. The brushes are fixed, and since the limits of commutation are so broadly defined, these motors operate noiselessly and sparklessly under varying loads, and with perfect regulation. A great feature of slow speed direct connected motors is one very seldom considered by those making a cursory examination of the subject. We will take for comparison motors running at 180 r. p. m. (a speed which is easily obtained by the Bullock motors), direct connected to line shafts or tools and other motors belted to line shafts or machinery and therefore running at, say, 1,000 r. p. m. Although of equal horse power, these motors differ greatly in their capacity of starting under load, for while the slow speed motor attains its full speed at 180 r. p. m., the high speed motor must revolve 1,000 times before it reaches its capacity. The slow speed motor, due to its characteristics, has a greater reserve capacity for overload and starting, as compared with rated horse power of the high speed one. Furthermore, the slow speed motors are so designed that their life and usefulness is much greater than that of the high speed ones, owing to heavier carrying capacity and low temperature limits.

While the cost of the direct connected motors is somewhat greater than that of the belted or geared motors, still the advantages are so considerable as to more than offset the extra expense.

At the present day, manufacturers are confronted by many problems which must be solved before the success of their undertaking is assured. The profits made are not so often in the articles manufactured, as in the small savings in power, and in the bi-products. The advantages of electrical transmission are most apparent in those cases where power is used intermittently, for, with the stopping of the motors, all expense for power ceases; whereas, belt transmission necessitates the operation of long lines of shafting and belting, even if but a small part of the tools or presses are at work.

The progress of science and of civilization all illustrate most positively the fact that the welfare of the human race depends on the elimination of useless or wasteful methods of production. To this end we see marvelous automatic machinery for turning out an infinite variety of articles. The prime movers, such as steam engines and water wheels, have become extremely economical in the use of coal and water power. It is now necessary to connect the prime mover to the machine by some means which does not nullify the good features of the prime mover and the machine, for which so much has been spent to obtain the highest efficiency. It is astounding to think that for years thousands of tons of coal have been expended for the mere friction load of shafting and belting, but the industrial world is now realizing most emphatically the necessity for retrenchment.

According to the tests made by Prof. Benjamin, of the Case School of Applied Science, Cleveland, O., the general average of power lost in factories and other establishments throughout the United States equals 51 per cent. of the total horse power generated by the prime movers in these establishments. Numerous examples of electrical transmission by direct connected motors have proven that one-half of this 51 per cent. can be saved, and it is in view of this wide margin of improvement, and the crying necessity for this new system of power transmission, that these electric motors have been designed and operated.

Among the numerous power applications in the East which the Bullock Electric Manufacturing Company has installed may be mentioned: Mergenthaler Linotype Company, Ryerson street, Brooklyn, N. Y.; Henry Heide, 78 Vandam street, New York; Young & Smylie, Brooklyn, N. Y.; New York Journal, direct connected motors operating three Hoe sextuple color presses; New York Herald, New York Sun, New York Times, Paterson Chronicle, Toronto Globe, San Francisco Examiner, Chicago Journal. Among the printing establishments may be noted: Frank A. Munsey; Kaufman & Strauss Textile Publishing Company; Winthrop Press, American Book Company, etc.

The Bullock Electric Company has done a large export business, and reports many favorable inquiries from England, France, Germany, Australia, Japan and China.

ELECTRICITY IN THE WOODWARD MINE, PA.

The Woodward mine of the Delaware, Lackawanna and Western Railroad at Kingston, Pa., is about to be equipped with electric haulage by the General Electric Company. The generating plant will consist of one 165-kilowatt dynamo directly connected to an American Ball engine. The circuits will be three in number. The first will pass down a vertical shaft 725 feet deep and will operate one ten ton locomotive in the Cooper vein. The two others will be carried down another vertical shaft 1,026 feet deep to operate two ten-ton locomotives in the Red Ash and Baltimore veins. These locomotives will be equipped with two 40-horse-power G. E. motors, and will handle trips of loaded mine cars each loaded car weighing about four and one-half tons.

It is estimated that this installation will show in operation a net saving of 29.5 per cent. over mule haulage, including a large reserve for depreciation, interest and mixed charges. The total output of these three locomotives will be about 3,800 tons per day, and the total length of trolley wire in the gangway will shortly reach four and a half miles.

NEW JERSEY TROLLEY STATISTICS.

A report of the State Board of Assessors giving figures about the electric and street railroads in New Jersey for the year 1896, shows total receipts $5,770,171, against $5,056,598 in 1895, an increase of $713,573. The expenditures were $3,546,168, against $3,431,931 in 1895, an increase of $114,236, and dividends paid $124,220, against $117,320 in 1895, an increase of $6,900. The number of miles of track in the State is 613; capital stock paid in, $38,235,150; funded debt, $36,420,493, and other debts, $4,279,396; total of capital and funded and unfunded debt, $78,935,039. The total cost of railroads, including the equipment and appurtenances, is put at $80,011,559, an average of $130,000 per mile of track.

ROENTGEN RAYS

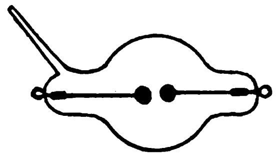
THE X-RAY ARC.

FRANCKE L. WOODWARD.

FOR the past three months I have been making a series of experiments in the X-ray field in the direction of obtaining the rays from the electric arc, and as the results obtained have at last been particularly successful, I thought the readers of the Engineer might be interested to know of them.

I believe it has been suggested that the ordinary arc light as used in our streets is a source of these rays. I have gone into the subject very carefully and under many different conditions, but have yet to find the slightest trace of the rays from this source.

I next turned my attention to the possibility of obtaining the rays from the enclosed arc in a high vacuum and my researches have led me to believe that this form of arc is the most plentiful and valuable source of X-rays to-day. I have used various forms of arc tubes, but the one shown in the accompanying sketch has given the best results by far. Platinum wires are sealed into the glass, but on the inside these are joined to aluminum terminals ending in a small bead of aluminum. The beads are separated a very small distance, varying from a sixteenth to half an inch, according to the strength of current used. This is one of the main points of difference from the ordinary Crookes tube.



WOODWARD X-RAY TUBE.

The second difference is the nature of the current. Instead of using the long spark from the secondary of an induction coil, or from a static machine, I pass this current of high potential through powerful condensers and use the short, thick, disruptive spark obtained therefrom. This necessitates that the anode and cathode be in close proximity in the tube. On the passage of a current of thin nature, the whole tube lights very brilliantly and an arc is produced between the anode and cathode which is the most intense source of Röntgen rays I have discovered.

The rays appear to have almost twice the penetrative power of any of the old type Crookes tubes which I have used, while the arc tube has the greater convenience that it may be made very small without diminishing its efficiency. I have in these tubes introduced a V-shaped piece of platinum foil between the aluminum beads with good results as in the Thomson type of Crookes tube, but if this is done the space between the aluminum beads is slightly increased.

[An apparatus of similar design was described by Mr. R. W. Wood in The Electrical Engineer of April 28, 1897, Mr. Tesla has also used the arc in vacuo.—Eds. E. E.]

SOCIETY & CLUB NOTES

POLICE TELEGRAPHERS.

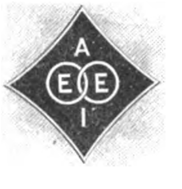
The executive committee of the International Association of Police and Fire Telegraph Superintendents met on May 17 at the Clarendon Hotel, Brooklyn, to arrange a place for the next annual meeting of the association. This association was organized last September, Frank Mason, superintendent, in Brooklyn City police telegraphs, being elected president. Those who attended the executive meeting included William Y. Ellett of Elmira, John W. Aydon of Wilmington, Del.; F. F. Zuleff of Paterson, Brown F. Flanders of Boston, H. F. Blackwell of Brooklyn, S. L. Wheeler of Springfield, Mass.; William Brophy of Boston, Adam Bosch of Newark, N. J.; Fred Pearce of New

York, R. W. Gordon of New York, W. L. Candee of New York, F. C. Mason of Brooklyn, N. Y.

President Mason welcomed the visitors and the business on hand was disposed of in short order. It was decided to accept the invitation to visit Nashville, Tenn., for the next convention, and Tuesday, September 8, was decided upon, this being the date of the "Old Time Telegraphers and the U. S. Military Telegraphers" meeting at the same place. The report of Treasurer Bosch shows the association to be in a good financial condition. The association is steadily growing in numbers. J. W. Aydon of Wilmington, Del., was elected a member of the executive committee.

AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS.

AT the meeting of the Executive Committee of the institute on Tuesday, May 18, the following associate members were elected: William C. Banks, electrician, Gordon-Burnham Battery Company, 82 West Broadway, New York City; Edward C. Clement, assistant examiner, Electrical Division, U. S. Patent Office, Washington, D. C.; A. Davidson, cable engineer and electrician, Central and South American Telegraph Company, Lima, Peru; Constant de Redon, consulting engineer, 27 Thames street, New York City; Sidney Hosmer, superintendent Underground Cable Department, Boston Electric Light Company, Ames Building, Boston, Mass.; Carl Kinsley, teacher of electrical engineering, Washington University, St. Louis, Mo.; John Neilson, superintendent of Interior Wiring Department, Larchmont Electric Company, Larchmont, N. Y.; Albert S. Richey, electrician, Citizens' Street Railway Company, 403 West Adams street, Muncie, Ind.



Ground of Dark Blue Enamel. The Interlocking Rings Represent Electricity and Magnetism.

The following associate members were transferred to membership: W. W. Nicholson, general superintendent Central New York Telegraph and Telephone Company, Syracuse, N. Y.; R. E. Richardson, electrical engineer, Chicago, Ill.; Edward B. Rosa, professor of physics, Wesleyan University, Middletown, Conn.

The annual business meeting of the institute was held at 12 West Thirty-first street, New York City, and was called to order by President Duncan at 4 P. M. The counting of the ballots by Mr. Hamilton and Dr. Pupin, who were appointed tellers, resulted in the announcement of the election of the council ticket as follows: For president, Dr. Francis B. Crocker, of New York City; for vice-presidents, Dr. A. E. Kennelly, of Philadelphia, Pa.; Mr. Chas. S. Bradley, of New York City and Mr. Dugald C. Jackson, of Madison, Wis.; for managers, Dr. Alexander Macfarlane, of South Bethlehem, Pa.; Mr. Gano S. Dunn, of New York City; Mr. W. F. C. Hasson, of San Francisco and Mr. Herbert Laws Webb, of New York City; for treasurer, Mr. George A. Hamilton, of New York City; for secretary, Mr. Ralph W. Pope, of New York City. The officers whose terms have not expired are: Vice-presidents, Chas. P. Steinmetz, of Schenectady, N. Y.; Harris J. Ryan, of Ithaca, N. Y.; Wilbur M. Stine, of Chicago, Ill. Managers, Chas. F. Scott, of Pittsburg; Bion J. Arnold, of Chicago; Carl Hering, of Philadelphia; Cary T. Hutchinson, John W. Lieb, Jr., and F. A. Pickernell, of New York City; Wm. L. Puffer, of Boston, and L. B. Stillwell, of Niagara Falls.

The reports of the council and the treasurer showed a net gain during the year of 38 members, the number in good standing on April 30 being 1,073. The treasurer's balance for the year on a balance sheet of $10,193 was $1,284. The institute has in property, $4,260; in the building fund, $956, and all told $6,662. The Institute having received $2,300 in life memberships since its foundation, and used the amount as current income, the treasurer is to set apart each year as long as necessary, the sum of $500 to be invested in a compounded membership fund.

The report of the committee on a new design for the Institute badge, which had been referred to this meeting by the Executive Committee, was taken up and thoroughly discussed resulting finally in the adoption of the new design recommended by the committee. Arrangements for the withdrawal of the old design and substitution of the new one will be made at an early date.

The paper on "The Synchronograph," presented April 21 by Dr. Crehore and Lieut. Squier, was then taken up for discussion. Mr. F. W. Jones opened the discussion, which was participated in by Dr. Kennelly and Mr. Delany. A paper on "The Application of Hyperbolic Analysis to the Discharge of a Condenser" was presented by Dr. Macfarlane. Owing to lack of time discussion was postponed until the general meeting, July 26.

The announcement by the tellers of the election of Dr. Crocker was greeted with hearty applause, and the president-elect was escorted to the chair where he acknowledged briefly his appreciation of the honor bestowed upon him.

At 7 P. M. the meeting adjourned and the members immediately reassembled at the "Arena," 41 West Thirty-first street, where arrangements had been made for the annual dinner under the direction of Mr. Herbert Laws Webb, chairman of the Committee on Papers and Meetings, and Mr. T. C. Martin. Although a sudden increase of about 50 per cent. of the number of guests necessitated the laying of 93 covers, the overflow was provided for, and the event passed off very pleasantly. Toasts were responded to by Dr. F. B. Crocker, Mr. F. W. Jones, Dr. M. I. Pupin, Dr. C. E. Emery, Dr. A. E. Kennelly, Mr. Ralph W. Pope, Mr. J. W. Lieb, Jr., Mr. Herbert Laws Webb, Mr. Nelson W. Perry and Mr. Joseph Sachs.

The exercises were interspersed with instrumental music by Mr. George Heli Guy and songs by Mr. Charles McL. Paine. Mr. Guy played a waltz of his own composition which he dedicated to the American Institute of Electrical Engineers.

ANNUAL MEETING OF THE NEW YORK ELECTRICAL SOCIETY.

MR. H. B. COX ON THERMO-ELECTRIC GENERATORS.

THE New York Electrical Society held its annual meeting at Columbia University on Thursday, May 20. The officers elected were: President, Dr. M. I. Pupin; vice-presidents, Gano S. Dunn, Max Osterberg, W. W. Ker, A. L. Riker, Willard E. Case, H. B. Coho; secretary, George H. Guy; treasurer, Henry A. Sinclair. The society has now 397 members. The president read a letter from the treasurer, in which was stated that a large number of members had failed to pay their dues. The president urgently requested that these arrears should be remitted forthwith, as the society has plans for extended work for next season, the carrying out of which will be impossible without proper funds. After the disposal of the business part of the meeting, Mr. H. Barringer Cox lectured on "The Direct Conversion of Heat Into Electricity," showing the present conditions of the practical relations between heat and electricity in regard to the direct conversion of the energy of fuel into current.

Following up the meeting which has attracted so much attention, at which Mr. Case experimented with his carbon consuming cell, Mr. H. Barringer Cox, who for many years has been working on the development of thermopiles, gave a very interesting lecture, which he illustrated with three of his thermo-electric generators, using gas flame as the source of heat. These generators, which have already been described in detail in The Electrical Engineer, consist of a number of thermo-electric couples of ingenious construction, grouped circularly around the flame, in which hangs a deflector or series of baffle plates. The elements are encased in fire resisting clay, backed up by a metal case, which forms the water jacket. From this small contrivance, which is about half the size of a silk hat, sufficient output is obtained upon the consumption of 2½ feet of gas per hour to run a small ordinary fan motor, or to operate such devices as electromedical sets, telegraph keys, X-ray apparatus, gongs and other devices.

There was an animated discussion, which was participated in by Dr. Emery, Dr. Crocker, Dr. Pupin, and Messrs. Mailloux, C. S. Bradley, Sachs, Ward Leonard, Lieb and others. Mr. Gano S. Dunn made some readings in testing the operation of the thermopiles, as there was a brisk dispute as to what the theoretical and the actual output of such devices ought to be, but it cannot be said that any clear result was reached. One of the thermopiles shown, a high voltage type, was rated by Mr. Cox at 10 volts and 3 amperes: two other of his ordinary smaller low volt type he rated at 4 volts, giving about 3 amperes, when measured on open circuit. One of Mr. Dunn's readings, short-circuiting the device through the Weston ammeter, showed 2.53 watts; another with the instruments and the running fan motor in circuit showed 3.75 watts.

AMERICAN STREET RAILWAY ASSOCIATION.

The sixteenth annual meeting of the American Street Railway Association is to be held in Convention Hall, Niagara Falls, N. Y., October 19 to 22, inclusive. A building 120 x 154 feet is being erected for the exhibition of street railroad supplies and for the meetings. Those attending the convention will secure their return ticket for one-third the price of the round trip fare. Mr. T. C. Penington, secretary-treasurer, 2020 State street, Chicago, will give full information in regard to accommodations and other particulars. Papers will be read on the following subjects: "Municipal Ownership of

Street Railways," "Modern Electric Railways; their Construction, Operation and Disadvantages," "Application of Electricity to Railroads now Operated by Steam Power," "The Best Method of Settling Damage Cases, and the Prevention of Accidents by the Use of Fenders and Otherwise," "Producer Gas for Use in Street Railway Power Houses and Gas Engines," "Storage Batteries for Street Railways," "Discipline of Employés," "Long Distance Transmission and the Use of Multiphase Current for Ordinary Street Railways."

NATIONAL ELECTRIC LIGHT ASSOCIATION.

Secretary G. F. Porter writes us: "Mr. Frank W. Hawley, chairman of the committee to receive and entertain Governor Morton at the opening of the electrical exposition last year, and whose energetic efforts in connection with the gun firing and the sending of messages around the world contributed so largely to the success of the exposition, has just called at this office upon his return from a trip to California. Mr. Hawley happened to be in San Francisco on the anniversary of the opening of the exposition, and in commemoration of the government gun firing on that occasion, which gave rise to so much agitation on the part of the city fathers of San Francisco, the military commandant at that post gave Mr. Hawley a very elaborate dinner at the Presidio, which was so timed as to be served at the exact moment at which the gun was fired just one year before. Mr. Hawley says that San Francisco is still talking of the excitement produced on that occasion, and also says that there is a strong feeling in that city in favor of an electrical exposition there next year."

PROGRAMME OF THE N. E. L. A. CONVENTION AT NIAGARA.

Secretary G. F. Porter has issued a very handsome pamphlet giving the programme of the convention. The assignments are as follows:

Tuesday, June 8, 1897. Meeting of the Executive Committee, at 9 A. M. Morning session, 10:30 o'clock. Address by President, Frederic Nicholls; report of Committee on Standard Candle-Power of Incandescent Lamps, Louis Bell, Chairman; report of Committee on Data, H. M. Swetland, Chairman; report of Committee on Rules for Safe Wiring, William Brophy, Chairman.

Afternoon session, 2 o'clock. Report of Committee on Finance, John A. Seely, Chairman; paper by J. B. Cahoon, "Standardizing Prices for Incandescent Light and Power;" topic, "Theft of Current and How to Deal With it;" paper by W. Worth Bean, St. Joseph, Mich., "Municipal Lighting;" questions and answers? ? ? What is it you wish to know? Executive session.

Wednesday, June 9, 1897. Morning session, 10 o'clock. Paper by C. L. Edgar, Boston, Mass., "Correct Method of Charging for Product;" paper by J. G. White, New York, N. Y., "The Niagara Power Transmission Line;" paper by Arthur Wright, Brighton, England, "Profitable Extensions of Electricity Supply Stations;" topic, "Commercial Results with Inclosed Arcs."

Afternoon session, 2:30 o'clock. Paper by Professor Chas. A. Carus-Wilson, McGill University, Montreal, Can., "The Induction Factor, a New Basis of Dynamo Calculation and Classification;" paper by Professor Elihu Thomson, Lynn, Mass., "Recent Progress in Arc Lighting;" paper by T. C. Martin, New York, N. Y., "The Daylight Work of Central Stations." Questions and answers? ? ? What is it you wish to know. Executive session.

Evening session, 8 o'clock, Lyceum Theatre. Paper by L. B. Stillwell, Niagara Falls, N. Y., "Niagara Power." (Illustrated with stereopticon).

Thursday, June 10, 1897. Morning session, 10 o'clock. Paper by B. F. Lamme, Pittsburg, Pa., "Polyphase Motors;" topic, "Best Efficiency for Incandescent Lamps;" paper by Lieut. F. Jarvis Patten, New York, N. Y., "Frequency Transformation;" topic, "Are the Large Arc Lighters Commercially Desirable?"

Afternoon session, 2:30 o'clock. Topic, "Lamp Carriers Other Than Ordinary Posts;" paper by C. F. Scott, Pittsburg, Pa., "Rotaries for Transforming Alternating into Direct Current." Executive session. Reports of secretary and treasurer of Executive Committee. Election of officers.

TEXAS ELECTRICAL DEALERS.

The electrical dealers and contractors of the State of Texas held their annual meeting on May 10, at Dallas. It was well attended. The officers elected were: President, J. E. Johnson, of Austin; first vice-president, C. W. Hobson, of Waco; secretary, W. G. Schuwirth, of San Antonio; treasurer, Thos. Hummell, of Dallas.

CANADIAN ELECTRICAL ASSOCIATION.

This body has arranged to have its annual meeting June 2, 3 and 4 at the Dufferin Cafe, Queen Victoria Park, Niagara Falls, Canada, and has provided an excellent programme.

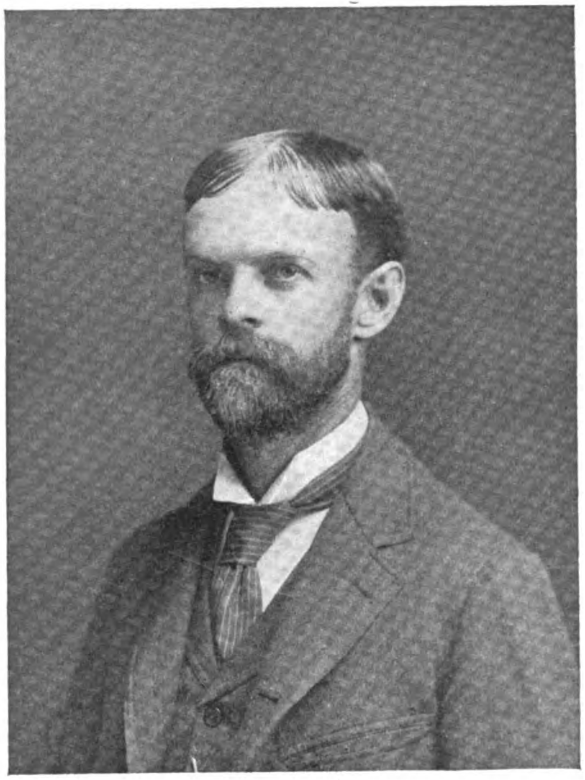
CHICAGO ELECTRICAL ASSOCIATION.

As a conclusion to one more year of serious work, the Chicago Electrical Association held its annual dinner last week, when 25 members were present out of a total of 45 in good standing. Mr. T. G. Grier presided as toast master, and speeches were made by Messrs. W. Clyde Jones, T. C. Gage and C. Marshall. After these set toasts, impromptu speeches and reminiscences were indulged in for some time, and before adjournment the association accepted the kind invitation of Mr. W. A. Harding, electrical engineer of the Calumet Electric Railway Company to a trolley party on that road, to take place some time in the summer.

PERSONAL

PROF. F. B. CROCKER.

We present herewith the latest portrait taken of Prof. F. B. Crocker, of Columbia University, New York City, who on May 18 was elected president of the American Institute of Electrical Engineers. The new president was born in New York on July 4, 1861, graduated from the School of Mines at Columbia, in 1882, with the degree of E. M., and received the degree of Ph. D. in 1895. He is well known as one of the designers of electric motors and other apparatus, and his name is borne to-day by the large enterprise known as the Crocker-Wheeler Electric Company, of Ampere, N. J. He has also written largely upon these subjects both in articles and in books. Prof. Crocker has been in charge of the electrical studies at Columbia ever since their separate establishment, first as chief instructor and now for some years as the Professor of Electrical Engineering. He has of late had a great deal of special and responsible work in connection with the engineering plant for the new university buildings on Morningside Heights. For two years Prof. Crocker was president of the New York Electrical Society, and he has for many years been in the active service of the institute, filling all the offices



Professor Francis B. Crocker.

except those of secretary and treasurer. In 1893 he did excellent work as general secretary of the International Electrical Congress at Chicago and editor of its transactions. In fact, there is no call to public duty in the line of his profession that Prof. Crocker has not responded to with zeal, intelligence and success of the highest order.

FRANK X. CICOTT.

Mr. Cicott is to resign his present position with the Ansonia Brass and Copper Company, this city, July 1, and will then carry out a plan he has been at work on for some time past of organizing a European company to handle the latest American electrical and street railway apparatus, as general agents abroad. Mr. Cicott, it will be well remembered, has had several years of commercial and journalistic experience in Europe and has exceptional facilities for embarking on this enterprise, for which he now deems the times ripe. He can be addressed for the present at 19 and 21 Cliff street.

MR. G. FRED PACKARD, until recently connected with the Fort Wayne Electric Corporation, as designing engineer, has severed his connection with that company and accepted a position, May 1, as electrician for the Akron Electrical Manufacturing Company, of Akron, O. While with the Fort Wayne company, Mr. Packard has designed a line of multipolar direct connected generators. Mr. Packard is now designing a new line of multipolar generators for direct connection and also a line of slow speed, belt-driven multipolar generators and motors soon to be placed on the market by the Akron Electrical Manufacturing Company.

MR. C. W. PRICE is the subject of a very cordial notice in the Fourth Estate, the article being accompanied by a nice half-tone portrait plate.

LEGAL NOTES

OKONITE CO. vs. HOLMES, BOOTH & HAYDENS.

A suit as above in regard to failure to deliver copper was recently disposed of in the New York Supreme Court by discontinuance. The complaint showed that in June, 1895, the Holmes, Booth & Haydens Company, as wire drawers, sold to the Okonite Company 300,000 pounds of copper at 12¼ cents, and after delivering 50,500 pounds, stopped further delivery The Okonite Company then, in September, 1895, purchased elsewhere the balance of the copper at 14 cents, and then sued the Holmes, Booth & Haydens Company for about $4,500, the difference.

An order discontinuing the suit has been entered, and we are informed that the Holmes, Booth & Haydens Company paid the Okonite Company about $2,800 in settlement.

ELECTRIC TRACTION ON THE NEW YORK METROPOLITAN.

Justice Beach in the New York Supreme Court has handed down a decision in three suits brought to restrain the Eighth Avenue Railroad Company, owned by the Metropolitan Company, from changing its motive power from horse power to electricity, and also raising the question as to whether the city has the right to purchase the road under the resolution of 1851, under which the franchise was granted to the company. Justice Beach denies the motion for the issuance of temporary injunctions, pending the trial of the suits, debarring the company from constructing the underground trolley, and holds that the city's right to purchase is "dead beyond hope of resurrection." He also says that the State Board of Railroad Commissioners has control of the regulation of street railroads, and that the Board of Electrical Control has no jurisdiction in the matter.

REED ELECTRIC CO.

Elmer D. Wilt has filed a bill in equity in Common Pleas Court No. 3, Philadelphia, against the Reed Electric Company, in which the court is asked to appoint a receiver to take charge of the affairs of the company and continue the business. The bill sets out that the company has expended over $50,000 in perfecting an electric storage battery invented by Charles J. Reed, who alone has the secret, and now alleges that the corporation has forfeited its right to his invention under the letters patent. It is asserted that the battery has proved successful and would earn large profits, but that the company is insolvent and has no more money with which to pursue experiments.

SYNOPSIS OF CURRENT ELECTRICAL LITERATURE

Edited by HERMAN A. STRAUSS.

Dynamos and Motors:

STARTING RESISTANCES.—By E. A. N. Pochin, B. A. Author considers at some length the different actions of motors when controlled by a liquid resistance, or when controlled with the usual multiple contact switch and a wire resistance. Elaborate example is given of a hundred ampere shunt motor working off 100 volt mains and having a load of such a nature that it will only start with the full working current. Author states following five desiderata of an ideal controlling switch: 1. It must prevent sudden switching on. 2. It must admit of slow switching off for regulating. 3. Instant switching off in cases of emergency. 4. It must automatically switch off the motor in case the supply fails. 5. It must be capable of the above operations without arcing at the main contacts. Author adds that many switches fulfil almost any three of these conditions, but none fulfils all five.—Lond. "Elec.," May 7, '97.

POLYPHASE MOTORS WITH VARIABLE NUMBER OF POLES.—By Rob. Dahlander. Author remarks that the methods in vogue for altering the number of poles of an asynchronous polyphase motor and hence altering the number of revolutions by changing the connections of the windings have been developed for motors with ring windings only and in the present article he explains with several very clear diagrams such a method for drum windings. Examples are cited and the advantages of the method here explained are said to lie in greater simplicity and the possibility of applying it to any polyphase motor by merely altering the winding.—"Elec. Zeits.," Berlin, May 6, '97.

Materials:

MICA: ITS UTILITY AND VALUE.—A short article defining mica, enumerating its various commercial uses and giving the general results of a few "breaking down" tests. Mica refuse, when passed through a disintegrator, and reduced to a flaky state, and then mixed with a proper adhesive substance, is found to be a most efficient covering for steam boilers or pipes. It is compared with "diatomite" and asbestos—equal thicknesses of each material being used and a gain for the mica covering of 12-lb. pressure, and 15 per cent. less heat outside the cylinders is obtained in one experiment. It is stated that mica in powdered form when properly prepared makes a lubricant which is unrivalled for all machinery requiring high speed, as it keeps the bearings absolutely free from heat, even at the greatest speed, while in the form of axle grease for railway cars and ordinary vehicles, it fills every possible requirement.—Lond. "Elec. Rev.," May 7, '97.

Traction:

MECHANICAL PROPULSION ON CANALS.—By Leslie S. Robinson.—Abstract of paper read before Inst. of M. E. Summary of the four different methods in use for the mechanical traction or propulsion of boats upon canals, viz.: 1. Propulsion of screws worked either by steam, by petroleum motors or by electricity. 2. Hauling upon a submerged chain or wire rope lying along bed of canal. 3. Attachment to an endless running rope working along canal bank. 4. Towing by a locomotive running along canal bank. Author considers the determination of the general resistance of a boat in a channel of restricted section. The resistance depends in some way upon the ratio which the wetted cross section of the canal bears to the immersed midship section of the boat and cites experiments. Permissible speeds are then considered and finally cost of such traction, the following table being self-explanatory:

Relative Cost of Transport by Railway and Canal.

	Railway.	Canal.
Maintenance of way	13	0
Maintenance of works	7	2. 3
Repairs of rolling stock	19	6.
Traction	16	8.
Traffic expenses	30	6.
General charges	15	15.
Interest on capital	100	33. 3
Total	200	70. 6

A second table of comparative costs of different modes of traction on canals is given. Author expresses no definite conclusion.—Lond. "Elec.," May 7, '97.

Wiring:

UNINSULATED PIPE FOR INTERIOR WIRING.—By V. Zingler. Author discusses the virtues of the different systems of interior wiring, stating that in such work there are two broad questions at issue, viz.: (1) Shall the pipe have an interior insulation? (2) Shall the pipe have no interior insulation? He states that the chief points under which any system of conduits should be discussed are the following: Cost of material, cost of labor, mechanical strength, chemical and electrolytic action, insulation, accessibility, durability. These various points are each considered.—Lond. "Elec. Rev.," May 7, '97.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MAY 18, 1897.

Batteries, Secondary:

ELECTRODE. W. Majert, Falkenberg, Germany, 582,936. Filed May 5, 1896.

Method of constructing electrodes for storage batteries providing a space between the frame and the mass allowing for the expansion of the latter.

Conductors, Conduits and Insulators:—

ELECTRICAL CONDUIT. J. J. Groshans,, Buffalo, N. Y., 582,910. Filed December 5, 1896.

Consists of two series of pipes one within the other, one series being sealed by a meterial impervious to moisture and the other series by a non-conductive material.

Dynamos and Motors:—

MACHINE FOR FORMING ARMATURE COILS. G. A. Grisell, Madison, Wis., 582,640. Filed November 16, 1896.

Details of construction.

BRUSH HOLDER. S. H. Short, Cleveland, Ohio, 582,883. Filed January 2, 1897.

Details of construction.

BRUSH HOLDER FOR DYNAMOS AND MOTORS. S. H. Short, Cleveland, Ohio, 582,884. Filed February 16, 1897.

Details of construction.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. J. A. Mosher, Chicago, Ill., 582,664. Filed December 17, 1892.

Comprises a solenoid, a movable core within, an armature under the influence of the magnetized core, but separated from it, and a spring acting upon the armature.

ELECTRIC ARC LAMP. J. A. Mosher, Chicago, Ill., 582,665. Filed January 19, 1894.

The regulation of the upper carbon is effected by means of a thermo-expansive wire.

ELECTRIC SEARCH LIGHT. S. W. Rushmore, Brooklyn, N. Y., 582,694. Filed January 11, 1896.

Carbon supporting and feeding devices.

Miscellaneous:—

ELECTRIC LOCK. H. Bezer, New Rochelle, N. Y., 582,615. Filed October 25, 1892.

A lock normally held in locking position, and remotely controlled means for retaining the lock out of locking position.

ELECTRIC ADVERTISING AND DISPLAY APPARATUS. J. L. Killmer, New York, 582,649. Filed March 2, 1896.

Comprises Geissler tubes arranged to represent letters and having a portion of the letters of a word different in color from the remainder of the word.

ELECTRODE. J. A. Deuther, Boston, Mass., 582,721. Filed August 19, 1896.

Electrodes with renewable sections at the point where the arc is formed.

GARMENT HOOK. J. J. Horan, New York, 582,742. Filed July 31, 1896.

Means whereby upon the removal of an article from the hook an alarm will be given.

MEANS OF AND APPARATUS FOR PREVENTING FORMATION OF ARCS WHEN OPENING CIRCUITS. T. Von Zweibergk, Cleveland, Ohio, 582,772. Filed October 29, 1896.

Consists in establishing a shunt circuit around the contact to be broken, then breaking the main circuit, then gradually commutating the current through the shunt circuit, and finally breaking the shunt circuit.

METHOD OF AND APPARATUS FOR TANNING. E. Worms, Paris, France, 582,891. Filed October 11, 1895.

The hides are immersed in tanning liquid in a closed drum submitted to agitation and to a gradual heating by electricity.

ELECTROLYTIC APPARATUS. A. E. Hunt, Pittsburg, Pa., 582,923. Filed December 4, 1895.

Comprises a number of vessels electrically connected in series, the several vessels having platforms in electrical connection therewith, so that they shall be maintained at the same electrical potential as the pot.

SLEIGH. J. S. Fritz, Columbus, Wis., 582,635. Filed December 30, 1896.

Embodies a motor driven traction wheel hung in a frame pivotally suspended beneath the body of the sleigh.

AUTOMATIC ELECTRIC GATE. J. M. Williams and T. P. Kinney, Danville, and H. W. Kinney, Lynchburg, Va., 582,889. Filed August 18, 1896.

A railway crossing gate operated by a motor in circuit with a generator, the motor circuit being controlled by track instruments.

ELECTROPNEUMATIC ORGAN-ACTION. H. E. Hobbs, Weston, Mass., 582,918. Filed May 21, 1896.

Details of operation.

Railways and Appliances:—

ELECTRIC RAIL BOND. G. H. Scott, Worcester, Mass., 582,698. Filed July 17, 1896.

Consists of the connecting rod and two bushings which fit over its ends and are adapted to be driven into the openings in the rails.

RAIL BOND. F. H. Daniels, Worcester, Mass., 582,849. Filed February 10, 1897.

Comprises a flexible body portion, and two terminals made separate from it and secured to it by pressure.

CIRCUIT BREAKER FOR TROLLEY WIRES. C. Hoff, Cincinnati, Ohio, 582,862. Filed January 22, 1897.

Composed of a suitable frame having downwardly turned forked ends; a pair of contact levers in the forked ends inclined toward each other and operated on by springs to open the circuit when the tension of the wire is lessened by breaking.

TROLLEY FOR ELECTRIC RAILWAYS. S. H. Short, Cleveland, Ohio, 582,882. Filed December 22, 1896.

Adapted for construction employing two overhead conductors.

INSULATING FISH PLATE. F. T. Fearey, Newark, N. J., 582,907. Filed March 22, 1897.

A fish plate having at its lower edge a hollow flaring extension to receive the flange of the rail, and provided with an insulating lining plate extending over the bearings and into the extension.

Switches, Cut-Outs, Etc.:—

ELECTRIC CONTROLLER. W. H. Morgan, Alliance, Ohio, 582,663. Filed November 14, 1896.

So constructed that the contact arm of the rheostat will be turned in the same direction when the operating lever is moved in either direction from its normal position.

ELECTRIC SWITCH. E. H. Wright, Chicago, Ill., 582,840. Filed March 13, 1896.

Especially designed for use in arc lighting.

Telephones:—

TELEPHONY. J. Absterdam, New York, 582,773. Filed May 27, 1892.

Consists in maintaining a magnetic field in suitable inductive relation to the line and setting up in the line independent, magnetic variations corresponding to speech. See page 569.

RECEIVER FOR TELEPHONES, PHONOGRAPHS, OR SIMILAR INSTRUMENTS. C. W. Dennis, King's Ferry, N. Y., 582,901. Filed August 7, 1896.

The receiver tube is provided with a hollow bulb, placed therein and with which the receiver proper is connected, the effect being to intensify the sound.

TELEPHONING FROM CARS. M. Garl, Akron, Ohio, 582,913. Filed January 10, 1896.

Comprises a field telephone, a portable pole provided with arms forming terminals of a circuit and arranged to make contact with terminals on the pole in close proximity to contact springs adapted to keep the circuit normally closed.

TELEPHONE TOLL APPARATUS. F. M. Archer, New York, 582,714. Filed April 30, 1896.

Operated by the insertion of a key; a main shaft adapted to send in a call when rotated in one direction and to entrap the key when rotated in the opposite direction.

THE STOCK MARKET

SLIGHT IMPROVEMENT.

THERE was very little improvement in general trade last week, but curiously enough it came from quarters that have long been stagnant, the northwestern cities of the Pacific slope. The average movement of merchandise was slow and dull. The like was true of the stock market due to tariff uncertainties, and anxiety about our relations with Spain.

During the week, Western Union sold to the extent of 22,405 shares and gradually regained its old status, rising to 78⅜ and closing at 77¾. General Electric was active, under bear attacks as to loss of certain desirable contracts, and went off to 28⅝, but closed at 30, there being sold in the week 22,308 shares. On the Boston market, American Bell stock has naturally become far more active than usual. The last two weeks have seen 3,348 and 1,146 shares dealt in, and the price shows a tendency to stay above 230. There is great curiosity as to the movements in the stock and its accumulation in certain hands.

In New York City, Metropolitan Traction stock has advanced as a result of the court decision which enables it to go on with its electrical equipment of Eighth avenue. The equipment of Manhattan elevated roads with electricity while not confirmed has been hinted again, giving strength to the stock up to 85⅝.

GAS ENGINES AND THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

We have received a communication from the Climax Gas Engine Company, Brooklyn, N. Y., in which they offer to place all the facilities of their shops at Erie, Pa., at the disposal of a committee of the National Electric Light Association about to meet at Niagara Falls. The company will furnish all instruments necessary to make a complete and accurate test of their gas engines, as well as of those of other makes to be found at Erie.

As Erie is only 100 miles from Niagara Falls, the Climax Company hopes the association will avail itself of this offer, made in good faith.

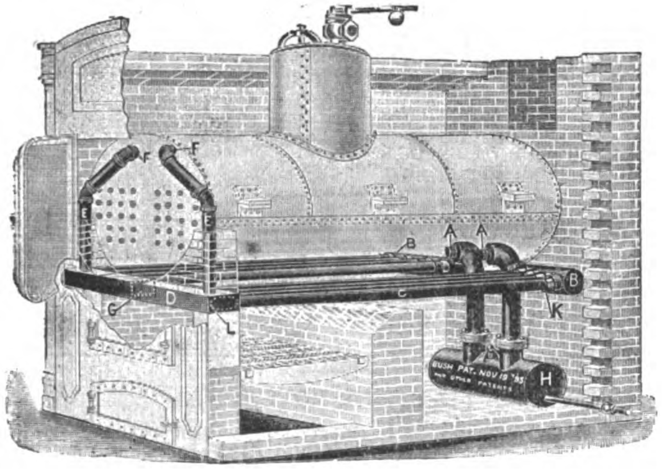
TRADE NOTES & NOVELTIES

THE HASCALL STEAM GENERATOR.

THIS is the name given the device shown in the engraving, designed to be placed under steam boilers generally, to increase their generating capacity and to make steam in the quickest, most economical and efficient manner. In this is comprehended a very great saving in the use of fuel, a dryer and more commercially profitable quality of steam than can be produced by any other means, an absolute freedom from scale or sediment formation in boiler, with a consequent longer life of the same.

While the engraving is self-explanatory to a large extent, we may say in addition that the generator is simplicity itself in its construction and principle of operation and presents no change of conditions to the engineer as regards firing or running the boiler to which it may be applied. It is accessible at all times without disturbing the boiler setting and the parts can be readily taken out, examined and replaced should this at any time be deemed necessary.

In attaching the generator, the rear head of boiler is tapped and connections made with close nipples at A A, which communicate with back headers B B. Expansion joints K permit the tubes to expand and contract freely without injury in any way to the boiler connections. The tubes C are screwed at the front into the water box or arch D, which is divided by a partition as shown by the dotted line at G. The front riser tubes E E, extend from the ends of the water box and enter the front head above the fire tubes and water level at F F.



The Hascall Steam Generator.

Circulation of water commences as soon as the fire is started, entering from the lower portion of the boiler into the generator at A A, and passing through the back headers B B, thence forward through the tubes C, which are immediately over the fire, into the water arch D, and up the risers E E, discharging at F F, into the steam space of the boiler. This circulation is constant and extremely rapid and always in the same direction, viz., from the lower point at the back end of the boiler to a point just above the water line in the front head. Such sediment as may be contained in the water tends to precipitate as soon as the temperature reaches the boiling point, and is carried in at A A by the rapidly flowing current, and, being of a greater specific gravity than water, continues on its downward course to the mud drum H, while the water turns to right or left, flowing through the piping as already described.

Thus, after heat has precipitated the foreign matter contained in the water, it is removed and isolated by reason of very rapid circulation and gravity, and the boiler and the generator remain perfectly clear and free from scale. In fact, every point of the interior of the generator and boiler is thoroughly washed by the rapid circulation of the water.

A section of piping was recently taken from one of these generators that had been used under a boiler in the building at the corner of Reade street and West Broadway, New York City, for four years. It was practically free from scale. In boilers where incrustation has already become a serious obstacle the attachment of the Hascall generator will, it is claimed, remove the incrustation and entirely prevent any further accumulation.

The generator is constructed of high grade material throughout and to meet all requirements of service for which it is designed, and is approved and insured by the representative boiler insurance companies. Data at hand covering an extensive use of the Hascall steam generator show that there is no difficulty in keeping steam at the pressure desired, that the saving in fuel is 10 to 30 per cent., or, using the same quantity of fuel as formerly, the capacity of the boiler is increased in the same proportion.

Substantiating this are the results obtained with the Hascall generator by many prominent users, among others the Standard Rock Candy Company of Brooklyn, N. Y. This concern has had one of these machines under a boiler 6 x 18 feet, and before its installation usually burned about 60 tons of coal per month. The generator has reduced this by 15 tons or 25 per cent., making the saving in fuel alone enough to pay for the generator in twelve months' time. Where formerly it took the engineer an hour to get up steam, but half that time is now required, and much less trouble is experienced in keeping up to the required pressure.

At Tarrytown, N. Y., one of these machines installed under one of the boilers at the water works pumping station, showed an increased efficiency in the boiler of nearly thirty per cent. A test made with the generator by the Brockton Last Company of Brockton, Mass., showed a saving in coal of over 20 per cent., and an increase of power considerably beyond anything the boilers ever produced before. This entire plant is now equipped with the device. It is claimed by engineers who have had experience that a horizontal tubular boiler with generator attached is the equal of the water tube type.

The Hascall Steam Generator Company, sole manufacturers, have branch offices in all the principal cities of the United States. The executive headquarters are at 66 Broadway, New York City, where models are at hand to demonstrate the principle of the generator and show its operation.

A LONG LIST OF SALES MADE BY THE ELECTRICAL EXCHANGE, CHICAGO.

THE Electrical Exchange, Chicago, report that their business is still on the increase, so much so as to render it necessary to have their hands work considerable overtime for some time past while in their repairing department they have been obliged to run day and night for over a week in order to get through the work in that branch of their business.

They have made the following shipments within the past few weeks: Marais Lumber Company, Grand Marais, Mich., one 1,000-light National alternator; Junction Iron and Steel Company, Mingo Junction, O., one 50-light Standard arc dynamo; Chicago Illuminating Company, Chicago, one 60-light Western Electric arc dynamo; one 750-light Slattery alternator; Mount Clemens Electric Company, Mount Clemens, Mich., one 50-light T. H. 12,000-c-p. arc dynamo; Lake Geneva Ice Company, Lake Geneva, Wis., one 25-light Western Electric arc dynamo and complete plant; Kenosha Electric Light Company, Kenosha, Wis., one 60-light Western Electric arc dynamo; F. D. Phelps, New Haven, Mich., one A-35 650-light T. H. alternating generator and complete plant; John A. Stewart, Cincinnati, O., one 60-light, 2,000-c.-p. Wood arc dynamo; Harrison Electric Light Company, Allegan, Mich., one 100-kilowatt 500-volt power generator; F. C. Stanford, Chatsworth, Ill., one 35-light Western Electric arc dynamo and lamps; Savannah, Thunderbolt and Isle of Hope Railway Company, Savannah, Ga., four W. P. 30 T. H. railway motors; Eastern Electric Equipment Company, Cleveland, O., two W. P. 30 T. H. railway motors; Raymond Bros. Impact Pulverizer Company, one 25-h.-p. 110-volt Westinghouse motor; Village of Mingo Junction, O., complete arc light plant; Sampson Steam Forge Company, Chicago, one 25-light Ball arc dynamo and complete plant; Boepple Button Company, Muscatine, Ia., one 18-h.-p. 110-volt Edison motor; Leslie & Gilbert, Hopkinsville, Ky., one 1,300-light Slattery alternating generator; Rockport Water Works Company, Rockport, Ind., one 1,000-light Brush alternating generator; Chicago Armature Company, Chicago, Ill., one 200-light T. H. incandescent dynamo; one 3-h.-p. 220-volt Jenney motor; H. E. Peltz, Cross Fork, Pa., one 225-light Sperry incandescent dynamo and complete plant, Herbert Simmons, Wellston, O., one 65-light incandescent dynamo; De Land & Co., Fairport, N. Y., one 7½-h.-p. 220-volt Eddy motor; R. W. Schmelz, Jacksonville, Fla., one 250-light incandescent dynamo and complete plant; Charles Doutz, South Clinton street, Chicago, one 10-h.-p. 500-volt Eddy motor; McPherson

Water and Electric Company, McPherson, Kan., one 250-light incandescent dynamo; Harris Automatic Press Company, Niles, O., one 100-light incandescent dynamo; Lyon & Healy, Chicago, one 5-h.-p. 125-volt C. & C. motor; Specialty Manufacturing Company, Milwaukee, Wis., one 10-h.-p. 220-volt Belding motor; Libertyville Electric Light Company, Libertyville, Ill., one 400-light Brush incandescent dynamo; Standard Lamp Company, Marion, Ind., one 400-light Brush incandescent dynamo; E. C. Bennett, Monadnock building, Chicago, one 75-light 110-volt Detroit dynamo; Carbondale, Ill., Electric Company, one 45-light 1,200-c.-p. T. H. arc dynamo. Also motors and dynamos of various units to the following: J. W. Berry, E. Washington street, Chicago; Elizabeth Iron Bridge Works, Elizabeth, Ill.; Fleager & Whittenberg, Georgetown, Tex.; Charles Gorton, Racine, Wis.; Pliny Norcross, Janesville, Wis.; Galveston City Railway Company, Galveston, Texas; Hoyt & Jackson Company, Norwalk, O.; Keelyn & Smith, Milwaukee, Wis.; John McQueen, Kirkland, Ill.; W. A. Mercer, Dawson, Ga.; Savannah Street Railway Company, Savannah, Ga.; Edison Vitascope Company, Water Valley, Miss.; Charles Wormley, Muscatine, Ia.; Pioneer Electric Works, Chicago; F. K. True & Co., Caxton building, Chicago.

WARD LEONARD ELECTRIC CO.

The factory of the Ward Leonard Electric Company was entirely destroyed on May 20 by a serious fire, which began in some adjoining buildings, and did great damage throughout the neighborhood. The Ward Leonard Company was well insured, and within 48 hours had leased a new factory building at the corner of Seventh and Clinton streets, Hoboken, which has ample facilities and is equipped with a first-class power plant. The Ward Leonard Company placed orders while the fire was in progress for tools and supplies required for beginning business in their new factory, which will be running with full force by the end of this week. The fire began between 7 and 8 o'clock in the evening. Fortunately for the Ward Leonard Company they were running night and day on account of having a large and increasing volume of business. This fact made it possible for the company to save all of its books, records, data, and other similar records, which are of the greatest importance to the company in its business, and which it would have been impossible to replace. On account of the preservation of these records the customers of the company will not experience any embarrassment in securing promptly any rheostats which have ever been heretofore made by the company. This is fortunate, since the company, in addition to its regular lines, did a very large business of a special nature for various electrical concerns.

WESTERN TELEPHONE CONSTRUCTION CO.

The Western Telephone Construction Company reports contracts for seven new telephone exchanges, involving the use of over two thousand telephones, since the decision was published. Some of these contracts are for furnishing apparatus in place of other makes. Among the contracts are 300 for Spartansburg, S. C.; 150 for Florence, Ala.; 300 for a new branch exchange at Fort Wayne, Ind.; 100 for Aledo, Ill.; 200 for Cameron, Mo.; and other places which the company does not care to disclose at present.

It is asserted by the Western people that their business will show a very large increase in the next three months, and, as an evidence of it they are putting in a large amount of new machinery and extending their capacity, once more, one-third their present manufacturing ability.

B. & O. MOTOR SERVICE EXTENDED.

The electric service of the Baltimore and Ohio Railroad Belt Line, which has heretofore run from the power house, corner of Howard and Hamburg streets, to the Mount Royal station, Baltimore, has been completed to Waverly, a distance of two miles. Hereafter freight trains will be drawn to that point by the electric locomotives. The object of the extension is to do away with the smoke nuisance in the annex, and also to enable rapid transit over the heavy grades which lie between North avenue and the York Road.

ESTIMATES WANTED FOR NEWPORT, IND.

What we would like to find out is what it will cost us to install an electric light plant. Ours is a small town of 700 or 800 people and has only two main streets running through the wn east and west, the cross streets being short. The east d west streets are about one mile long and in the main par the town there is about as much territory south and north here is between the two streets. The creek is on the north and a large hill on the south preventing it from ever being any wider. From this description if you or your readers can give us an approximate estimate of the cost of putting in such a plant as will light our town and cost of running it after in and the cost of arc lights and incandescent lights per month it will aid us very materially in arriving at a definite conclusion.

WM. RHEUBY,
By Order of Committee.

Newport, Ind.

RUSHMORE MARINE DYNAMOS AND PROJECTORS.

THE Rushmore Dynamo Works, of Jersey City, who have for years made a specialty of marine equipment, have brought out a line of direct connected sets or steam dynamos in which every detail has been perfected to meet the exacting requirements when working in cramped quarters in hot, damp engine rooms where the temperature is often beyond human endurance.

Fig. 1 shows one of the new generating sets of 20 kilowatts capacity built in the same frame with their new type engine of 25 horse power at 350 revolutions per minute. The magnet is a continuous steel casting with form-wound coils. The armature is of the iron clad type wound with continuous copper bar on a new wave system, insulated with mica, and is guaranteed against short circuit when saturated with sea water. There is no shaft from the rear of the armature, but the engine flange couples directly to the armature core body, insuring perfect alignment. The dynamo has but one bearing which is self-oiling, of large capacity with patent settling chamber.

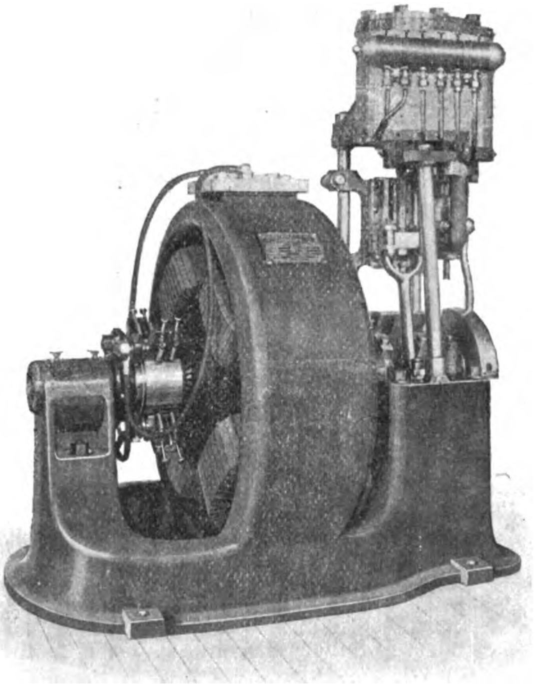


FIG. 1.—THE RUSHMORE MARINE GENERATOR.

The engine is of new design with the frame of steel forgings, highly finished. The crank shaft with counterweights and couplings is forged in one piece, machined all over and drilled hollow. The coupling which is forged with the shaft bolts directly to the armature and the bearings are extra large to carry the extra weight. The automatic cut-off governor is very powerful and regulates within one per cent. All wearing surfaces are lubricated from a single tank oiler with sight feeds leading to every wearing surface. Machines are so perfectly balanced that they will run at double the rated speed without vibration and may be mounted on bulkhead or grating without foundation. The same type of generator is also made for belt driving in sizes up to 150 kilowatts.

As is well known, the Rushmore Works build a complete line of high power projectors and they now have a complete line ranging in sizes from 10 to 72 inches in diameter, taking from 5 to 300 amperes. They are now building a number of 30-inch naval projectors with electrical distant control mechanism for the large battleships.

Fig. 2 shows one of the latest type projectors with parabolic lens as used on the transatlantic liners. The Rushmore Works have the only lens making plant in the country and they have recently completed a magnificent machine weighing several tons which will grind lenses up to 6 feet diameter with an accuracy heretofore considered impossible, and they will shortly complete a 72-inch light for long distance signalling which will take a current of 300 amperes.

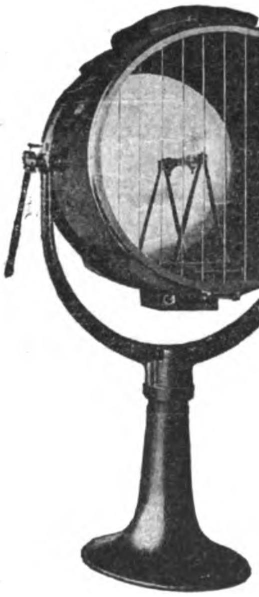

Fig. 2.—The Rushmore Marine Projector.

ADVERTISERS' HINTS

H. T. PAISTE COMPANY, Philadelphia and Chicago, observe that "money saved is money earned," and that one of the surest ways of saving it is by buying their cut-outs, of which they carry as many as twenty-six styles of open and covered.

THE WESTINGHOUSE MACHINE COMPANY, Pittsburg, Pa., quote from the report of the superintendent of the Carnegie Library Building in which are installed three 12" and 20" x 12" Westinghouse compound engines. The entire plant represents an outlay of $60,000 and but $71.43 was expended on repairs, or less than 20 cents a day for the year.

THE GENERAL ELECTRIC COMPANY call attention to the fact that 33,000 of their magnetic blow-out lightning arresters are in use.

L. A. CHASE & COMPANY, 161 Fort Hill Square, Boston, Mass., publish a very gratifying letter from the Summerside Electric Light Company, Summerside, P. E. Island, on the merits of their circuit breaker.

THE LYNN INCANDESCENT LAMP COMPANY, Lynn, Mass., give several sound reasons why their renewed lamps are fully equal to new lamps.

BULLOCK ELECTRIC MANUFACTURING CO. continue to advertise direct connected motors for machine tools. This company have made this branch a special study from the start and they are better than ever qualified to equip plants of any size at short notice.

C. H. McEVOY, Lowell, Mass., furnishes cords for a large variety of purposes, such as telephone, medical battery and switchboard uses.

THE BOSTON GEAR WORKS, 34 Hartford street, Boston, Mass., manufacture gears of every style and size.

KROTZ, ALLEN & KELLY, Springfield, O., advertise the K. A. K. system for street, elevated and trunk line electric railways. Its details are described more fully elsewhere in this issue.

MR. ELMER P. MORRIS, of 15 Cortlandt street, New York, has a useful little wire calculator, which he is sending out to the trade as a novel advertisement. It consists of two dials, and gives the number of lamps and distance in feet that the current has to be transmitted; the size of wire necessary can readily be discovered. Mr. Morris will send one of these calculators to anyone sending him a stamped envelope.

NEW YORK NOTES

MR. ROBERT B. COREY, of New York, who is so well known in the electrical business, has just been appointed by the Simplex Electrical Company, of Boston, as sales agent for their wires and cables in New York City and State, Pennsylvania, New Jersey, Maryland and Delaware. Mr. Corey will have his office at 711 Havemeyer building, New York, and will be pleased to hear from any of his numerous friends in want of quotations on this class of goods. Mr. Corey's large acquaintance amongst the electrical fraternity throughout the whole country should make him a valuable acquisition to the staff of the Simplex Company.

THE ROUSSEAU ELECTRICAL FACTORY, beyond the Harlem, was visited by fire on Friday last, when about $5,000 damage was done. Two of the men were badly burned. The fire was due to an explosion of kerosene in the bicycle plant. Mr. Rousseau has energetically gone ahead in resuming his electrical and other work.

WARREN WEBSTER & CO., manufacturers of feed water heaters and proprietors of the Webster system of heating for buildings, have removed their New York office to 322 Broadway.

THE ELECTRO-VISUAL TELEGRAPH COMPANY, of New York City, has been formed with a capital stock of $50,000, by M. C. Ebel, F. S. Pierson, G. L. Mason and C. Spriggs, of New York City, and M. G. Walford, of Hackensack, N. J.

DR. W. M. HABIRSHAW, of the India Rubber & Gutta Percha Insulating Company, has just returned from a long European trip in good health and spirits.

MR. R. EDWARDS, JR., of Edwards & Co., has just returned from an extended trip through the West and reports having met with unusually good success, booking a large number of orders for their new fog motor gong of which they are making a specialty. Edwards & Co., have accepted the agency for the American Electric Fuse Company, manufacturers of Maxstadt fuses and fusible cut-outs.

MR. H. F. NOYES, patent solicitor, Syndicate Building, New York City, has brought out an excellent little brochure in stiff linen cover, giving a great deal of useful and practical information as to patents and patent office procedure. No fewer than 33 forms are included.

MR. A. D. FRENCH, 200 Broadway, New York, has removed to larger offices in the Edison building, 44 Broad street, where he can be found between 10 and 4 in regard to all matters connected with lumber supplies for electrical work, such as octagonals, cross arms, creosoted lumber, piling or conduit. He has put on storage in New York a large supply of octagonals and cross arms for immediate delivery.

AMERICAN IMPULSE WHEEL COMPANY 120 Liberty street, New York City, will be glad to send to any address a copy of their very interesting pamphlet on water wheel work, and a copy of their form for filling up with data by any one desirous of making an inquiry as to the use of a water power anywhere.

MR. H. A. STRAUSS has been awarded the contract for the electric wiring installation of the Essex County (N. J.) Hospital for the Insane, at Overbrook, N. J. The contract calls for complete installation of basement, first and second floors, including the dome. Mr. Strauss is in the market for material for the above installation. Iron armored conduit will be used throughout.

Mr. Strauss is also in the market for materials for a 4½-mile electric railway complete, including track, overhead construction, and power station with engines, boilers, dynamos, etc.

BUFFALO, N. Y.—From their St. Petersburg office the Buffalo Forge Company, Buffalo, N. Y., have recently received an order for two engines of the inclosed type running in oil. Both are of the same size (8 x 10), and they are to be shipped to St. Petersburg, Russia. These engines will be used for electric lighting. The engine department of this company has been very busy and unable to keep up with orders. A new five-story building, 210 x 60 feet, is being built.

MR. F. R. UPTON, general sales manager of the National Tube Works, McKeesport, Pa., was in New York City last week. He has recently issued an admirable little book on their steel trolley poles, and finds daily more demand for their tube specialties in electrical lines, where his great familiarity with the questions arising gives him a great advantage.

THE ELECTRO-CHEMICAL STORAGE BATTERY CO have removed their factory from Belleville, N. J., to 35 Ge street, New York City. They will retain their offices in Johnston Building, Broad street. The company report ar cellent demand for their batteries.

THE KINGS COUNTY ELEVATED ROAD, in Brooklyn, is to be reorganized and equipped with electricity, using Mr. F. J. Sprague's system of "unit" control.

THE GOODYEAR VULCANITE COMPANY, 353 Broadway, New York, report installing a 200-horse-power steam engine in their works at Morrisville, Pa. The demand for their hard rubber goods for electrical and mechanical purposes is steadily increasing necessitating enlargements of their factory in all directions.

NEWARK, N. J., is rejoicing in some beautiful new Brill cars put on by the Consolidated Traction Company. The old cars seat only 21 passengers; the new ones are 25 feet long and seat 36 people.

ST. LOUIS, MO., is renewing its lighting contracts and has before it a proposition to buy a city plant in 20 annual instalments.

WESTERN NOTES

THE WESTERN ELECTRIC COMPANY, Chicago, owing to the great increase of business in their electrical supply department, are making considerable extensions in their warerooms so as to enable them to give adequate space to that part of their business. They are fitting up in very tasteful style quite a considerable part of the second floor of their South Jefferson street building for this purpose. One room in particular, in which samples of the great variety of supplies carried by this company are to be displayed, will be illuminated by handsome chandeliers which will show off the goods to advantage.

THE MIDLAND ELECTRIC COMPANY, a new manufacturing concern just formed in Chicago, has opened an office at 1564 Monadnock Building. Mr. Joseph Kettlestrings, the manager of the company, has long been identified with electrical interests in Chicago, and withdraws from a large electrical manufacturing company to take charge of the interests of the company he now represents. The new firm will manufacture a superior line of alternating arc lamps and transformers, as well as give their attention to general electrical engineering work.

MR. GEO. F. BRUNT, of East Liverpool, O., has purchased the entire interest of his partner, Mr. C. F. Thompson, in the porcelain electrical supply business formerly carried on by Brunt & Thompson. His intention is to continue the business with a full line of high grade porcelain supplies, and to win for them a reputation higher even than that already enjoyed by these specialties.

OKOLONA, MISS., is about to put up a water works and electric light plant. The engine contract for the electric plant has been awarded to the Ball Engine Company, Erie, Pa.

THE F. & C. MOTOR SWITCHES make up a new line of goods which the Electric Appliance Company have recently added to their already complete and extensive stock. The F. & C. switches appear to fill the bill for a low-priced motor switch in capacities of 35 and 65 amperes. The Electric Appliance Company will be pleased to send special prices on these goods on application.

MR. CHARLES A. ARCHER, who was formerly with the Edison General Electric Co., in Chicago, and also the Adams-Green Co., has become associated with the Electrical Construction Co., of Madison, Wis., which has its office in the same place as the Electrical Supply Co., of which Mr. S. W. Burch is manager. Mr. Burch, whose energy is well known throughout the Northwest, is working as hard as ever for business, and states that they are getting a good share of what trade there is to be had in their territory.

THE DAYTON FAN AND MOTOR COMPANY, Dayton, Ohio, report business very good. Large orders have been received this season, and their products are enjoying everywhere well-deserved commendation.

MASSILLON, O.—A. Y. Gordon, manager of the Farmers' elephone Company, and the inventor of an adjustable transter bracket, has sold the exclusive right to use his patent he American Electric Telephone Company of Chicago.

ORED LAMPS.—A satisfactory coloring for incandesamps has been long sought. The Electric Appliance y are placing on the market a new coloring, known as ctrical Chemical" lamp coloring, which it is claimed lamps in such a way that it is difficult to distinguish n genuine colored glass lamps. An examination of done with this coloring shows that it is a superior

M. HAMILL, Jr., vice-president of the Brush Elecpany, was in New York last week. He has accomery successfully the heavy task of transferring the Brush manufacturing plant and several hundred men to Lynn, and has already got the wheels going, to fill recent large orders for Brush apparatus, particularly the big arc lighters.

THE CHRISTY FIRE CLAY COMPANY, St. Louis, Mo., have recently undergone a reorganization of their management, on account of the death of Mr. J. B. Clements, the vice-president and general manager. The officers now are: C. M. Christy, president; C. T. Farrar, vice-president; W. C. Morris, general manager and treasurer; F. P. Jones, secretary; R. D. Hatton, assistant secretary, and V. P. Ring, traveling representative.

ST. LOUIS, MO.—The bondholders of the Edison Electric Illuminating Company, of St. Louis, have voted overwhelmingly in favor of a plan of reorganization to be perfected by the issuance of $4,000,000 in bonds, the plan being to give a 5 per cent bond and ten shares of cumulative 5 per cent preferred stock for two 6 per cent outstanding bonds. Of the new issue, $2,000,000 will be devoted to taking up present bonds; $1,100,000 to taking up the bonds on the Missouri Electric Lighting and Power plant; $400,000 to providing for the floating indebtedness, and $500,000 to the construction of the company's conduits. Of the $4,000,000 new stock, $2,000,000 is to go to the present bondholders; and $2,000,000 will go to the present stockholders on their payment of $6 per share. The latter payments will liquidate the interest which became due in February last.

THE AMERICAN ELECTRIC VEHICLE COMPANY is to have a new factory, it is said, at New Chicago, Ind., between Hobart and Liverpool, where a new town is being laid out. They are said to have orders on hand for $50,000 of electric carriages. The Excelsior Carbon Works are also to go to New Chicago, it is stated.

INDIANAPOLIS, IND.—The Commercial Telephone Equipment Company, with a capital of $25,000, has filed articles of incorporation. The object of this company is to build and equip local telephone exchanges throughout the States of Indiana, Michigan and Kentucky. The following are the officers and directors: President, Delos Thompson, of Rensselaer; vice-president and general manager, Edgar H. Andress, of Lafayette; secretary, Charles E. Mills, of Rensselaer; treasurer, Thomas J. McCoy, and superintendent of construction, James F. Watson, both of Rensselaer.

H. B. CAMP COMPANY, Aultman, O., writes us: "We have the contract for furnishing, laying and doing the complete subway work for the Delaware and Atlantic Telephone Company, at Wilmington, Del. We have our men now on the work. We are also at present shipping our vitrified clay conduit pipe to Dallas, Texas; two companies in Boston, Mass.; three companies in Chicago, Ill.; to Buffalo, Des Moines, Pittsburg, Cincinnati, Cleveland, Philadelphia, Detroit and Toronto. Our manufacturing capacity is 35,000 feet daily at our three plants. The prospects are quite flattering for a large business this season."

MR. FRANK J. SPRAGUE will be in charge of the electrical equipment of the Chicago South Side Elevated Road, and will there demonstrate his plans for the operation of such roads under the varying conditions of large and small loads, with single and multiple car units. Sargent & Lundy are the construction engineers.

MR. H. W. KILBOURNE, general sales agent of the Ohio Storage Battery Company, Cleveland, O., reports an increasing demand for the Ohio battery, and that the factory is busy filling orders.

MR. J. L. MORGAN, city electrical inspector of Kansas City, Mo., has been instructed to make a series of careful tests on the electrolysis of the local water pipes, with a view to their better protection.

DIXON, ILL.—The Dixon Power and Lighting Company have just installed a 16-horse-power Edison motor in Baldwin & Son's grist mill in this city.

MR. THOS. G. GRIER, of the Western Electric Company, Chicago, has been experimenting on Babbitt and composition metal for street car bearings and has succeeded in producing a high grade, long-wearing bearing. Mr. Grier has recently issued a new edition of Wiring Tables, in which is explained how they are made and how to use them. The book has met with very well deserved success, and is highly creditable to the author.

BROWNLEE & CO., of Detroit, the well-known manufacturers of wooden poles and cross arms, report a very active demand for cross arms this spring. Their sales during April were over one hundred carloads.

THE DYER ELECTRIC COMPANY, of Chicago, has certified to a change of name to the Dyer Tower and Motor Company, and to an enlargement of the objects of incorporation.

THE WILLIAMS-ABBOTT ELECTRIC COMPANY of Cleveland, O., has been incorporated by F. M. Kirk, S. D. Latty, H. T. Latty, J. A. Williams, S. B. Abbott and S. Albert, Jr., with a capital stock of $10,000. Its intention is to manufacture telephone supplies.

NEW ENGLAND NOTES

ARMINGTON-SIMS ENGINE COMPANY, of Providence, R. I., have received an order from the Edison Electric Illuminating Company, Bellefonte, Pa., for engines to replace those destroyed in their recent fire. An order has also been received from Columbia University, New York City, for two heavy duty self-oiling cross compound direct connected engines, for the new university buildings on Morningside Heights.

BOSTON EDISON COMPANY. The stockholders of the company have subscribed for 3,240 shares at $120 per share, for the extension of the business. Another annex station is to be built.

BERLIN IRON BRIDGE COMPANY, of East Berlin, Conn., have a contract for furnishing the steel roof for a large store house which is to be erected by the Waterbury (Conn.) Manufacturing Company. This building is 54 feet wide and 144 feet long. The side walls are of brick. The roof will be supported by steel trusses. The covering is to be corrugated iron lined with the Berlin Company's patent anti-condensation fireproof roof lining.

PHILADELPHIA NOTES

THE RIDGWAY DYNAMO AND ENGINE COMPANY, Ridgway, Pa., in addition to the large list of sales published a week ago, report the following business: One 15 x 16 engine, Wellston Coal Company; one 13 x 12 D. C. engine to 60-k. w. generator for Lester Manufacturing Company, Lestershire, N. Y., and two 100-k. w. generators for David S. Brown & Co., New York City.

ERIE, PA.—The Erie City Iron Works will, it is stated, add dynamos and motors to their boilers and steam engines. The new machine will be the design of Mr. C. J. Sturgeon, formerly of the Keystone Electrical Works, and Smith Hill Elevator Company. The building of motors is to begin at once.

SOUTHERN NOTES.

VIADUCT MANUFACTURING COMPANY, Baltimore, Md., are pushing the sale of their warehouse or interior telephone system, in its improved automatic form. After the conversation is over, the act of placing the receiver where it belongs, automatically moves the switch to its normal position. Any station can call any other independently. Desk sets or wall sets are supplied with this system, as desired.

SUMTER, S. C.—C. T. Mason, of Sumter, and P. E. Blow, of Knoxville, Tenn., have incorporated as the Telephone Manufacturing Company, which will make telephones at Sumter. The capital stock is $5,000.

GALVESTON, TEX.—The Brush Electric Light and Power Company have placed their order with the Ball Engine Company, Erie, Pa., for a 450-horse-power horizontal cross compound engine, which is to be direct connected to a Stanley alternating machine.

JOHN WEDDERBURN & COMPANY, 618 F street, Washington, D. C., have issued some very interesting literature in regard to patents and their own large share in securing them for hundreds of clients. One pamphlet, illustrated with views of their offices and of Federal buildings in Washington, tells how to get a patent. The other suggests 1,000 lines to work on. Both contain numerous testimonials for clients and well known public men.

SAVANNAH, GA. is to have a new electric light and power plant. A petition for the incorporation of the Edison Electric Illuminating Company of Savannah has been filed in the Superior Court. The petitioners are Charles A. Stone and Edwin S. Webster, of Boston, Mass., and George J. Baldwin, of Savannah. The period of incorporation named is twenty years with the privilege of renewal. The pincipal place of business is to be in Chatham county. The amount of capital stock to be actually paid in is stated at $100,000, and the company is to have the privilege of increasing its capital stock to any sum not exceeding $500,000.

BALTIMORE, MD.—The Blue Line is now being transformed from cable to electricity, and the old cable power house will be converted into a car barn. The American Car Company of St. Louis is supplying 16 new open cars.

CAMPBELL & ZELL COMPANY, Baltimore, Md., have sold 1,200 horse power of boiler capacity to the Metropolitan Traction Company, Washington, D. C. This is their fifth order from that source.

MR. E. J. WESSELS, General Manager of the Standard Air Brake Company, sails for Europe on the steamship Majestic on June 2, in the interest of the air brake business which has substantially increased from the time he first went over the ground in person. The Standard Air Brake Company closed the month of May by securing an additional order from the Colonies for twenty-eight air-brake outfits for electric motor and trail cars, and another order for additional motor-car air brakes. In view of the fact that their air brakes have been in use in the Colonies for nearly three years, this latest order emphasizes the success of the apparatus.

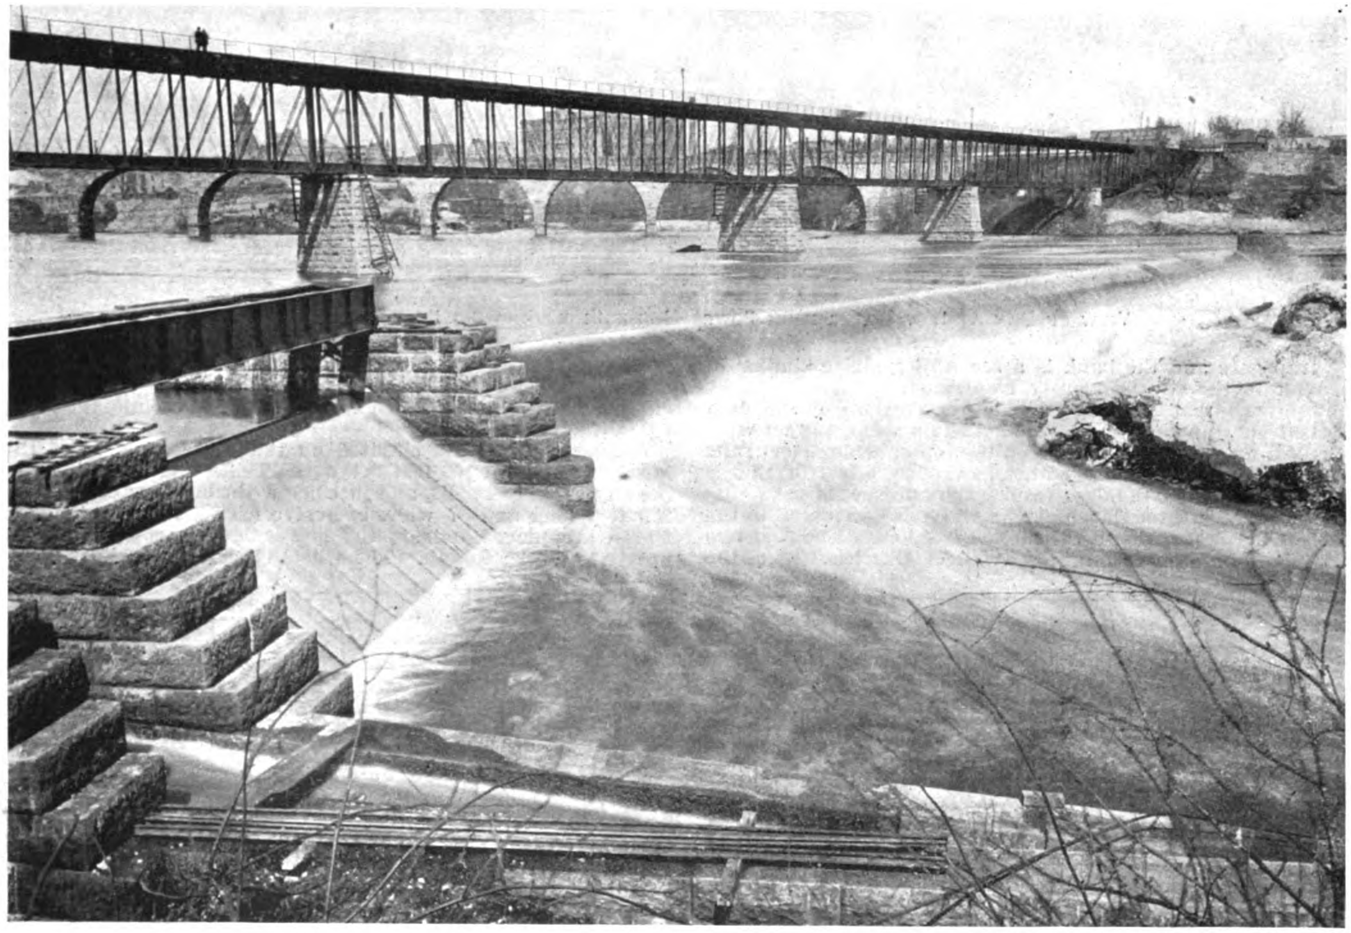
The Electrical Engineer.

Vol. XXIII. JUNE 2, 1897. No. 474.

POWER TRANSMISSION

THE ST. ANTHONY FALLS ELECTRIC POWER TRANSMISSION AT MINNEAPOLIS.

THE completion of the hydraulic work at the Falls of St. Anthony has been announced. It marks the achievement of a great enterprise, in scope and character second only, perhaps, to the hydraulic work which has made the waters of Niagara the servant of a vast territory. Within a short time the waters of the Mississippi will be propelling the street cars of two cities with an aggregate population of 360,000 and will, at the same time, operate large electric lighting plants and furnish current to large motors in the big mills, as well as to innumerable smaller motors in Minneapolis and St. Paul. In 1895 the Pillsbury-Washburn Flour Company, of Minneapolis, commenced the construction of a dam for the purpose of utilizing the fall of 20 feet in the rapids of the Mississippi River immediately below the Falls of St. Anthony. During the past winter the 10,000 horse power to be generated by a dam was leased for forty years to the Twin City Rapid Transit Company. That corporation being desirous of making an early use of the power, the work was pushed vigorously.



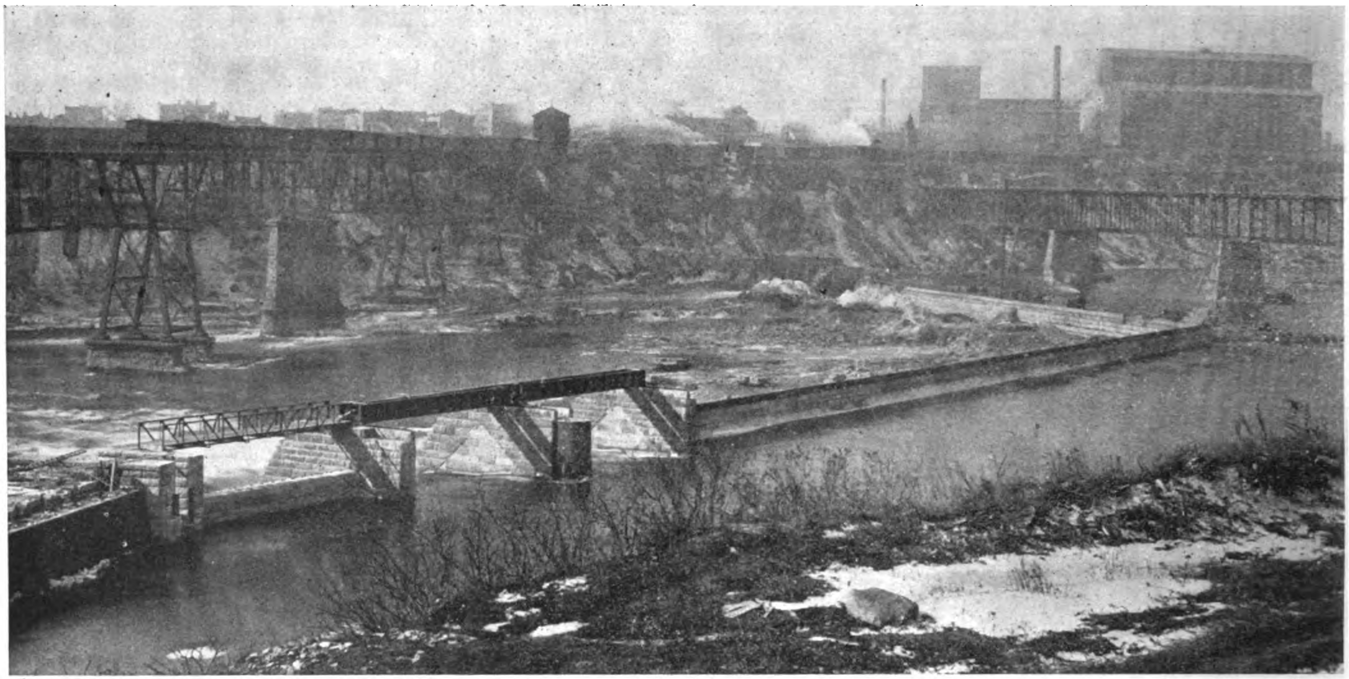
View of Dam at High Water from West Side of Mississippi.

The enterprise has been carried out by the St. Anthony Falls Water Power Company, which owns a strip of land on the north side of the Mississippi stretching from north of Sixth avenue to south of Eleventh avenue. It is along this strip, between Sixth and Eighth avenues that the head race has been built while from Eighth avenue to the opposite point of the river, between the Western Railway Bridge and the Tenth Avenue Bridge the dam has been thrown.

The engineer in charge of the work is Mr. De La Barre, who for many years has had charge of the extensive improvements of the St. Anthony Falls Water Power Company. The hydraulic motor equipment, that is, the turbines and accessories, are from the works of the Stilwell-Bierce & Smith-Vaile Company, of Dayton, O. The electrical equipment will be furnished by the General Electric Company, and the system of generation and distribution will be a combination of the direct current and the three-phase alternating current system.

THE POWER HOUSE.

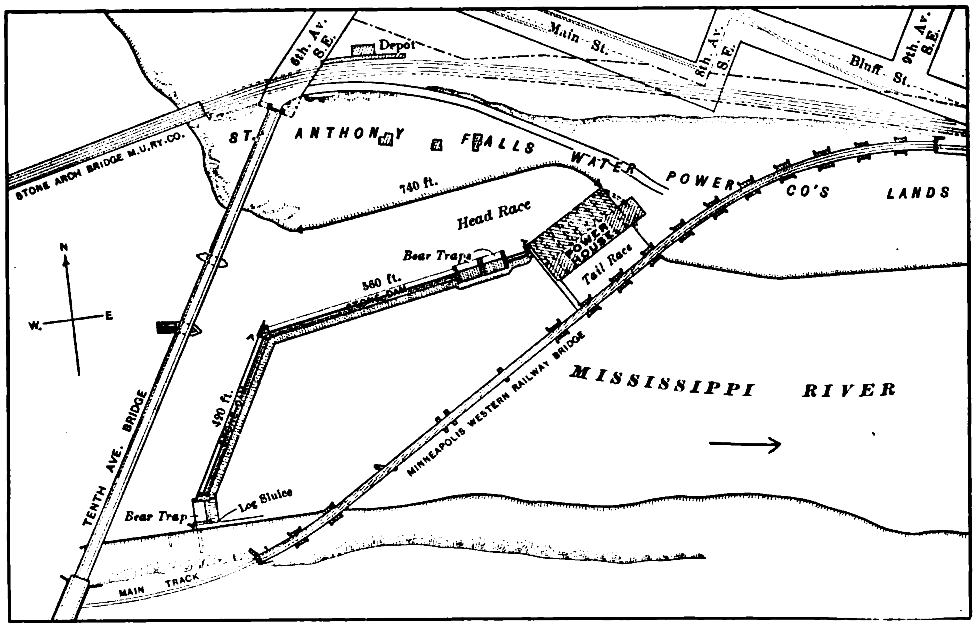
The power house is built out in the river in a southwesterly direction. At the river side of the power house and just outside is a log sluice, six feet wide and 200 feet long with stone wall and concrete bottom covered with railroad iron laid in cement. From the log sluice the dam starts in a westerly direction up the river. This section is 50 feet long, 12 feet 6 inches above the bed of the river and extends below the bed of the river 16 feet. Between this section and the second are two bear trap gates each 50 feet long operated by water-pressure. They are built of steel decked with wood and move between solid stone piers 8 feet in width, 40 feet long and 25 feet high. The first section of the dam is of solid masonry, the coping and down stream face being laid on granite; the balance of the wall is of blue limestone. The second section is 444 feet long and 14 feet high above the river. Its construction is similar to that of the first section, the coping, however, being of steel and concrete in lieu of granite. The third section runs in an almost southerly direction for a distance of 366 feet. It is 13 feet above the bed of the river and has about the same general construction as sections one and two, granite coping being used. Between this section and the bank of the river is another bear trap gate 50ft. wide, similarly constructed to the two on the power house side of the river and between the bear trap gate and the bank is a second log sluice similar in character to the one previously mentioned.



View of Dam at Low Water from Power House Side, Showing Bear Trap Gates.

The down stream face of each of the sections of the dam and the bear trap gates is provided with an apron 15 feet wide made of a level bed of concrete on the top of which steel rails have been laid and securely anchored. The effect of this is to protect the top of the dam from wash and scouring.

The head race through which the water is conducted to the wheels is 217 feet wide and about 600 feet long. The first two sections of the dam forming one wall of this head race, the retaining wall on the northeast side of the river forming the other.



Map of St. Anthony Falls Power Transmission Plant, Minneapolis.

Where the head race meets the wheel chambers a substantial steel racked frame the full width of the race is erected. This supports a rack 207 feet long which is constructed to prevent the passage of floating material to the wheels. In order, furthermore, to prevent the clogging of the rack with the natural accumulations of floating material in the race an automatic rack cleaner will be installed which will travel the entire length of the rack and will be operated by an electric motor directly attached to the machine. The dèbris gathered by this machine is deposited on a traveling belt conveyor and discharged into a sluice which in turn discharges into the river below the power house.

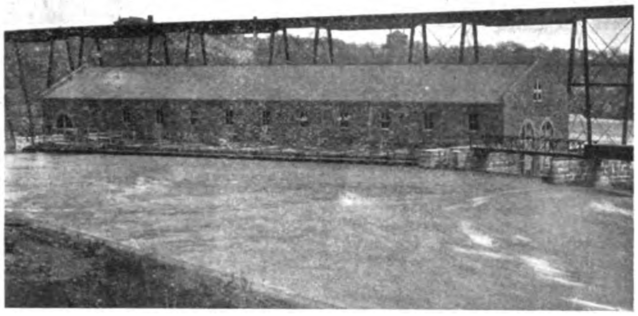
The power house is situated on the northeast side of the Mississippi, about 100 feet below the Tenth Avenue Bridge, in the city of Minneapolis, and just below the milling district. It is 250 feet long and 57 wide, exclusive of the wheel chambers. These are placed outside the power house proper and run nearly its entire length. The wheel chamber is 43 feet wide, making the width of the power house and wheel chamber 100 feet. The building is of substantial fireproof construction, the frame work and roof trusses being of steel, the walls of hollow tile 16 inches thick and the roof of tile covered with cement, finished with roofing slate and galvanized iron cornices.

In the building on the upper side of the wheel chambers, 18 feet above the generator floor is a gallery. This is 207 feet long and 10 feet wide and in it will be erected the switchboards, the transformers and electrical instruments together with the general offices, and the drafting room. The gallery is reached by two iron stairways, one at each end of the building. The interior of the building will be finished in hard wood and the walls in white. The main building is lighted by 15 windows, each 12 feet wide and 25 feet high. The switchboard gallery is lighted by 10 windows, 4 feet wide and 7 feet high.

To facilitate the handling of the machinery a 20-ton traveling crane will run on girder rails the full length of the building. It will be operated from a small cage built on the crane itself.

THE WATER WHEELS.

The capacity of the plant will be 10,000 horse power in 10 units of 1,000 horse power each. Each power unit consists of four horizontal Stilwell-Bierce & Smith-Vaile turbines, each 42 inches in diameter and running at a speed of 130 revolutions per minute. In addition two pair of 21-inch horizontal wheels will be used to drive two exciters. These are so arranged that they can be operated independently of the other machines.



BACK OF POWER HOUSE DURING HIGH WATER.

The turbines will be governed by Lombard governors.

The wheels are erected in chambers, four wheels in each; these chambers are of masonry with partition walls 4 feet thick; the flume head walls are each 7 feet 6 inches thick and hold flume head thimbles each 8 feet in diameter closed with heavy cast iron covers which carry the stuffing boxes through which the wheel shafts pass to the generator couplings. The wheels are supplied with water through two head gates in each chamber, each gate being 8 feet wide and 9 feet high, raised and lowered by a hoisting attachment on the deck of the wheel chamber. Each wheel chamber is provided with a separate and independent tail race, the full width of the wheel chamber, 100 feet long. The tail race passes underneath the power house and discharges into the main tail race below.

This is 207 feet wide and 100 feet long. The bottom or floor of the tail race, together with the foundation for carrying masonry in the building foundations is a solid bed of concrete 220 feet square and 2 feet thick.

THE ELECTRICAL EQUIPMENT.

The electrical equipment will consist at first of seven 700-kilowatt generators and two 100-kilowatt exciters, all directly connected to the turbine shafts. Five of the 700-kilowatt machines are three-phase alternators furnishing current at 3,450 volts; two are direct current generators furnishing current at 650 volts. The current from three of the alternators is intended for St. Paul and passes to the high tension switchboard and thence to step-up transformers where it is raised to 12,000 volts. At St. Paul it is stepped-down to 387 volts and is turned into rotary converters, which furnish direct current at 600 volts to the St. Paul Railway system. For the Minneapolis line the current at 3,450 volts is passed through step-down transformers and through rotary converters reaches the railroad feeder circuits also at 600 volts. Five rotary converters, each of 600-kilowatt capacity, are installed at the Third avenue power house, and the Thirty-first street and Niollat Station in Minneapolis, and at the Eagle street station at St. Paul, a distance of ten miles from the power house, and all run in parallel with the present generators.

The direct current machines are of the standard General Electric Company eight-pole railroad type. The main switchboard in the generating station will be of the panel type and will consist of two generator panels, eight feeder panels and one totalizing panel for the direct current system, one panel for each exciter, a panel for each alternating current generator and six alternating current feeder panels. The lightning arresters which will be employed to protect the transmission, are of the Wirt alternating current type made up of large metal cylinders mounted on porcelain base with a spark gap of 1-32 in. between each cylinder. The transformers are of the air blast type each of 233 k. w. capacity, to be erected upon platforms beneath which will be a chamber air tight with the exception of the ducts leading to the interior of the transformers. The air will be furnished by a 60-inch blower driven by a 5-horse-power 4-pole motor.

The rotary converters are 12-pole machines running at 400 revolutions and both transformers and rotary converters are very similar to those used in the transmission between Niagara Falls power house and the power house of the Niagara street station of the Buffalo Street Railway. The transmission will be through underground cables laid in 4-in. conduits of vitrified clay, and this is not the least unique feature of the whole transmission.

The power will be used primarily to drive the cars of the Twin City Railway Company, but in addition an extensive power service will be taken by the mills of the Pillsbury-Washburn Company. At present 750 horse power will be taken for the "A" Mill and 250 horse power for the "B" Mill. Furthermore, it is probable that the pumping of the municipal water system will also be operated by motor, driven by power from St. Anthony's Falls.

MECHANICAL

THE PRINCIPLES AND CONSTRUCTION OF WATER WHEELS.—IV.

BY W. E. WINES.

(Concluded.)

THE governor shown in Fig 13 is one of the eight distinct types of water wheel governors made by the Lombard Water Wheel Governor Company. Their three distinctive features are as follows:

First—There is at all times a reservoir of energy in the shape of air compressed under high pressure, which can be used instantly to move the water wheel gates, whether the water wheel is running or not; from this it follows that the time occupied in moving the gates to the correct position is independent of the speed of the water wheel itself.

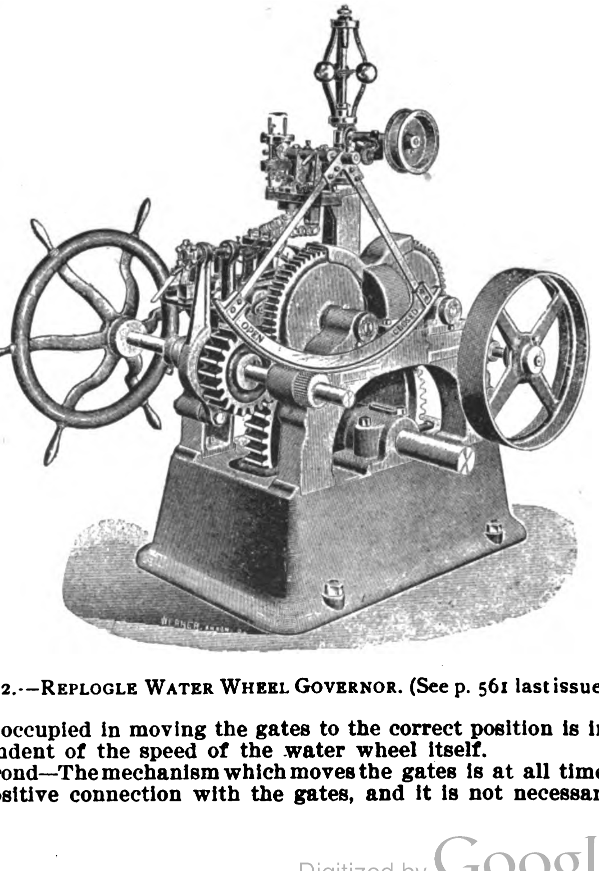


FIG. 12.—REPLOGLE WATER WHEEL GOVERNOR. (See p. 561 last issue.)

Second—The mechanism which moves the gates is at all times in positive connection with the gates, and it is not necessary to engage ratchets or clutches when a load change occurs, and the position of the gates must be changed. An hydraulic piston moving in an incompressible fluid is at all times positively connected with the water wheel gates and moves them with great promptness when occasion requires. Upon the whole load going instantly off a water wheel these governors will close the gates in about three seconds and the motion is smooth and easy and entirely free from hammering effects.

Third—These governors do not race. That is, no matter how great the load change they will not open nor close the water wheel gates too far, but will stop them at the correct position for the new load.

The makers claim for these governors that with well designed water wheels properly set they can give a speed regulation equal to that which could be obtained with a first-class steam engine working under like conditions of load variation.

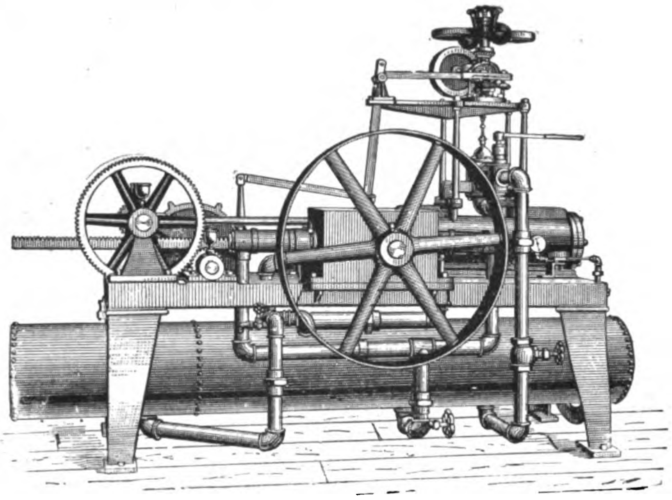

FIG. 13.—LOMBARD WATER WHEEL GOVERNOR.

To sum up briefly it may be said that the modern water wheel is vastly more efficient than any steam engine that ever has been or probably ever will be constructed; that it is equally reliable, less bulky, lighter in weight, less expensive both in first cost and in maintenance, and is capable of such nice regulation as to compare favorably with the best steam engine practice. When it is remembered that an insignificantly small portion of the world's water power is at present developed and that by the aid of electricity this power may be transmitted any distance that is ever likely to be required, it is seen that the water wheel is destined to become a potent factor in our industrial development and as such is well worthy the study of those who either are or aspire to be members of the engineering profession.

ELECTRIC TRANSPORTATION

THE TROLLEY CAR AFTER A DAY'S RUN, AND ITS REPAIRS.

BY DANIEL O'MAHONY.

IN car barns containing fifty or sixty cars there are usually three cars, or sometimes more, pulled in off the road for "trouble," and a number reported by the motormen for the same cause; a car is kept on the road so long as the trouble is not serious enough to disable it. When trolley cars came into to use at first, with the old systems, it looked as if they were going to be a failure. It was not strange to see fifteen cars pulled in on a wet day for controller trouble alone; but there have been great improvements made and it is astonishing how small an amount of trouble is now experienced in keeping them in order, considering the mechanical and electrical details, which are liable to get out of order.

When a car comes in after the day's run, it is not necessary to inspect every part of it, as some parts only require inspection twice a week, but such parts as brushes, etc., require inspection every night. The parts of a car that are liable to get out of order and require constant looking after, are the controllers, motors, lights, switches, rheostats, wiring, brakes, trolleys, wheels, sand boxes, fenders, journal boxes, gongs, bells, registers, etc. Some of those have many individual parts; for instance, the motor has the armature winding, commutator, shafe and bearings, brush holders and brushes, fields, motor leads, etc.

At present the motor gives more trouble than any other part. The armature often gets grounded either in the winding or the commutator; the band wires come off by touching the fields, when the bearings become worn; the fields get grounded; short circuit in the fields, armature winding or commutator; lead wires burned off, etc. The magneto is usually used to locate trouble, excepting short circuits in winding, which, of course, must be found with a Wheatstone bridge, or some other apparatus for measuring resistance.

The controller, which of course is a most important part, was at first of a very poor design. A shower of rain would often cause it to be charred or burned out; the mechanical parts were clumsy and weak, and it took a great amount of time and labor to keep them in condition for the road. The controller now in use is the best part of the equipment. There are several types on the market at present. I believe a certain make to be the best, for the following reasons: It has the least number of parts, it cannot be reversed with the power on; it starts on the first point with either motor cut out; the rheostat also being in the circuit, it can be used to stop the car in case of emergency, without reversing the motors, and having electric magnetic devices for blowing out arcs, it very seldom gets burned out. There is only one slight fault found in it by the repairmen. That is the ratchet pawl, which is not an essential part. The wheel attached to the pawl or its spindle wears out in a very short time, and is sometimes difficult to replace, without taking the controller apart. The controller requires very little attention, if the contact fingers are properly adjusted so as to touch the rings on the drum as they ought; and these rings or segments of wire on the drum require to be rubbed with a bit of waste dipped in vaseline or common motor grease. If this is neglected the surface of the rings and contact arm get like files, and the friction becomes so great that it is very hard to turn the controller handle, and they will wear themselves out in a short time, while they will last about twelve months if lubricated. The controller never gets "charged," which used to be such a menace to motormen, as well as the passengers, as the back is grounded.

There are usually a number of jam nuts on the adjusting screws and binding post screws which, if left loose, will cause great trouble; in some cases the controller handle cannot be turned, which, of course, disables the car, and very often causes wires and parts of the controller to be burned off.

A car is sometimes pulled in for not starting on the first point of the controller. This is caused by a motor lead being burned off; the motor leads are the short wires leading from the cables to the motors. From constant shaking and vibration these wires get broken and arc, which in a short time completely burns them in two. If the car is properly wired this may be avoided to a great extent. This can be done by putting the wires in a short piece of hose, in place of bringing them through separate holes in the car body, and leaving them exposed to the rain. The wet weather very often will cause one of these wires to be burned off. The rain causes the wood work to be grounded, and when the insulation gets worn off the wire will keep arcing until its fuses. A car often gets "charged" in the same way, or any wire that may happen to get its insulation off and touch some metal part of the body will charge it, which will give a shock to anyone coming in contact with it. Sometimes a car will be charged so that every time a person raises his foot from the floor he receives a shock when the canopy switches are turned on.

There is not much trouble experienced with rheostats. A rheostat sometimes gets so hot that it actually sets fire to the car. This is caused by the motorman keeping the controller set on the rheostat points, which is against the rules.

The lights give a great deal of trouble, as they get out of order easily, usually in the chandelier. The wires get the insulation rubbed off and short-circuit the lamps. The lamp socket sometimes gets loose and arcs, burning itself out. The lamps themselves get bad, and as the lamps are in series an open circuit will, of course, prevent any of them lighting. In cars that are wired, however, without the chandelier, like the Brooklyn Bridge cars, the lamps last a long time without getting out of order. Lightning also damages the lighting circuits, but it usually fuses the lightning arrester, which of course disables the car, as the trolley wire and ground are connected when the switches are turned on. In some cases, although seldom, the controller is struck by lightning and very badly damaged. The trolley poles ought to be removed from the wires in the car houses during a thunder storm. A number of cars have been known to start out of a house and run some distance without the controller being set during a storm.

The repairs to the truck and mechanical parts are also considerable. The greatest trouble is experienced with the wheels, brakes, and bearings. The wheels get flat, which will often occur when sand has been used. When the wheels get flat the only remedy is to take the pair out and replace them with new ones; this requires considerable labor, and sand, therefore, should be used as sparingly as possible.

The brakes are reported for being out of order oftener than any other part of the car. Of course a bad brake affects the motorman more than any other part of the car; in fact, it would be hard to find a harder day's work than braking a car all day with bad brakes. The brakes should be inspected every night, as the constant wearing of the shoes necessitates a lot of adjustments, particularly as the shoes do not wear evenly, and as the shoes must be kept a certain distance from the wheels, the brakes will not work right if the shoes are too near or too far from the wheels, the chain too long or short. The brake chain sometimes breaks, which might cause a very serious accident, particularly on a hill. There is a way of stopping a car in case the brake and power give out together, which every motorman should understand. That is, with the canopy switch turned off, to reverse the controller and set it on the last point.

Another trouble experienced with brakes is the falling down of the brake rigging, which not alone disables the car, but is sometimes very dangerous for the motorman, as shoe, etc., may get under the wheel and cause the brake shaft to revolve with great force, the handle striking the man if he is near it.

The bearings also require a lot of labor and expense to keep them right. The armature bearings are of the most importance, as the armature has but a very limited amount of space to revolve in. The wearing down will, of course, cause it to rub against the field pieces.

A car is often reported for bad trolley. There is a great deal of work on trolleys; keeping them straight, replacing wheels, particularly in the case of sleet, when sleet wheels are put on to prevent the wire getting covered with ice. The jumping of the wire from the trolley is the greatest trouble with this part, and the repairman often makes a mistake in fixing this, believing it is due to a bad wheel. It is seldom a bad wheel that causes the pole to jump; it is usually in the base that the trouble lies. The tension may be too weak, and the springs may want to be taken up, so as to get a greater pressure against the wire.

The register for counting the fares often gets out of order, and is often the cause of having a car pulled in. It sometimes will not ring the bell, or register the fares correctly, and as the company believe that it is the most important part of the car, its getting out of order causes the car to be disabled as much as if the two motors were bad. The other parts of the car, such as the feeders, gongs, etc., require but little repairing.

In big companies the small repairs including the brake shoeing of cars is done in the car barn, but the heavy work is done in the repair shops. For instance, the Consolidated Traction Company of New Jersey, have their shops half way between Jersey City and Newark. In these shops the machinery and facilities are very perfect, and as the company has the services of a very competent electrical engineer (many of the labor-saving machines used in the shops being his invention), the expenses are reduced to a minimum. The cars are overhauled in these shops and all the heavy repairing is also done here, such as taking out armatures, winding armatures, taking out flat wheels, renewing bearings, turning down commutators, and all lathe work. There is also a large amount of carpentry, painting and blacksmithing work done here. In every car barn there is at least one man who thoroughly understands the wiring and mechanism of a car, and a number of men to do cleaning, greasing and oiling and small repairs, inspecting, etc.

When all the cars are in, the report book is looked at to find what cars are reported for trouble, which must get attention first. The particular part of the car that is bad is usually reported, but the motorman cannot be relied on, as he sometimes arrives at extraordinary conclusions. Thus, on one occasion, a man reported a gear wheel broken; he thought he could hear it pounding all day; nothing, however, was found to be the matter with it. A car is often reported for motor trouble, whereas the controller is to blame, or vice versa. The only time a motorman can really be depended on for information is when a car is "charged," particularly when he has no gloves on.

Sometimes a car which comes in "O. K." will not start in the morning. This may be fixed sometimes by all hands giving the car a push for a foot, when the car will be found all right. The trouble might have been a dead rail. Sometimes a bit of paper is put between the wire and the trolley wheel to try if the electrician is qualified. The cars begin to start in the morning from about five until seven. The car barn during these hours would be a good place for persons suffering from loneliness of spirits, etc. It is often a scene of confusion, particularly when the cars get blocked. Every one seems to be calling for something, trying his gong or his vocal qualities, in winter, the electric snow plow and sweepers of a bad car with its fireworks and explosions sometimes adding to the scene.

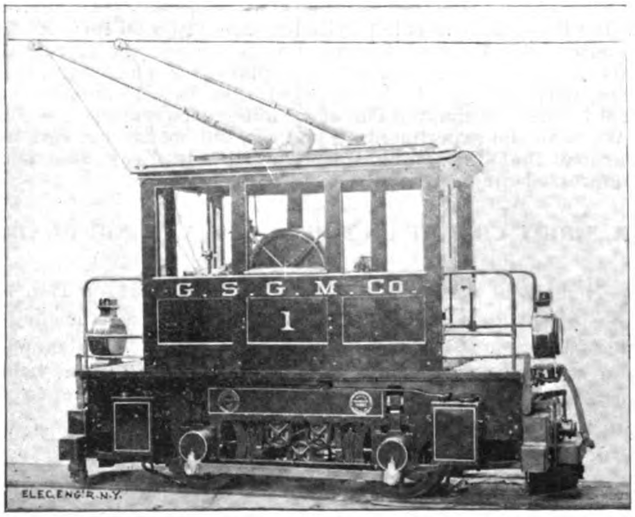
THE GOLDEN SCEPTRE MINE ELECTRIC RAILWAY.

THE accompanying engraving illustrates an electric locomotive designed by Mr. F. W. Darlington for the Golden Sceptre Gold Mining Company.

The specifications for this locomotive required it to have a capacity to haul a train of cars weighing in all 35 tons up a maximum grade of 5 per cent. The following data give the details:

Weight	not less than	30,000 lbs.
Drawbar pull at 8 miles per hour	" " "	4,500 "
" " at start	" " "	6,000 "
Diameter driving wheels		33 in.
Extreme width		52 "
Gauge		36 "
Weight of rail		45 lbs.
Two Westinghouse motors	each	50 h.p.

The grades of the road are excessively long and severe, the road being nearly eight miles in length. After about 1,000 feet of slight down grade, it begins to rise at about a 2.25 per cent. grade for 9,500 feet; then for 3,700 feet at 2.43 per cent., and beyond, 3,400 feet at 4.2 per cent.; finally the road takes a steady climb of 5 per cent. for a distance of no less than 20,400 feet, or nearly 4 miles. In fact the total rise is nearly 1,600 feet in less than 8 miles. For a steady pull this almost approaches the Jungfrau Railway in Switzerland, now in course of construction.

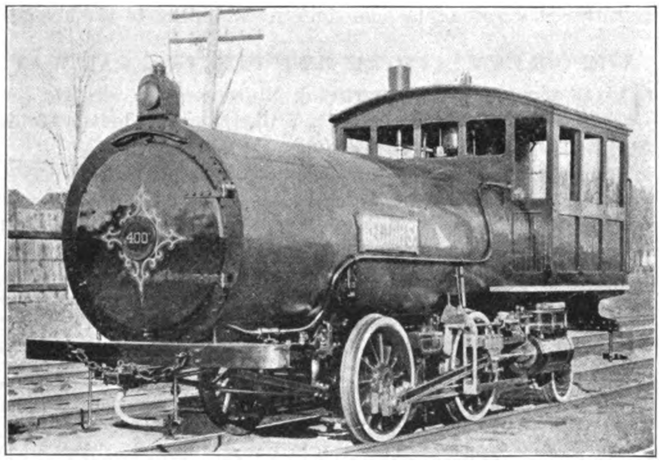


ELECTRIC LOCOMOTIVE, GOLDEN SCEPTRE GOLD MINING CO.

THE HARDIE COMPRESSED AIR LOCOMOTIVE FOR THE NEW YORK ELEVATED RAILROAD.

NOTWITHSTANDING the fact that even steam surface roads, such as the New York, New Haven and Hartford, and the Pennsylvania Railroad, have adopted electricity, on a part of their lines, and notwithstanding that elevated railways in Chicago and in Liverpool, England, have been in successful operation for years, the management of the New York elevated railway system still finds itself unable to make up its mind as to the "practicability" of electric traction. In the meantime it will give the use of its track to carry out an experiment with compressed air locomotives.

The accompanying engraving, taken from the Street Railway Review, shows the Hardie locomotive which will be shortly put to work on the company's system. In general appearance this machine much resembles the ordinary steam locomotive. The space usually occupied by the boiler, however, is taken up by the storage tanks for the air and by the reheater. On this locomotive the air is stored in 36 tubes of Mannesmann rolled steel; they are 9 inches in diameter and of varying lengths, from 13½ to 21 feet. The charging pressure is 2,000 lbs. per square inch. The air is led from these tanks through the reheater, in which water is stored at an initial temperature of 350 degs. Fahr., and after passing through three reducing valves is admitted to the cylinders at a pressure of 100 lbs. The working cylinders are 13½ x 20 inches. The American Air Power Company, which controls the Hardie patents has erected a compressing plant for charging at 100 Greenwich street. It is expected that this locomotive will haul 5 cars and make a run of 13 miles between charges.



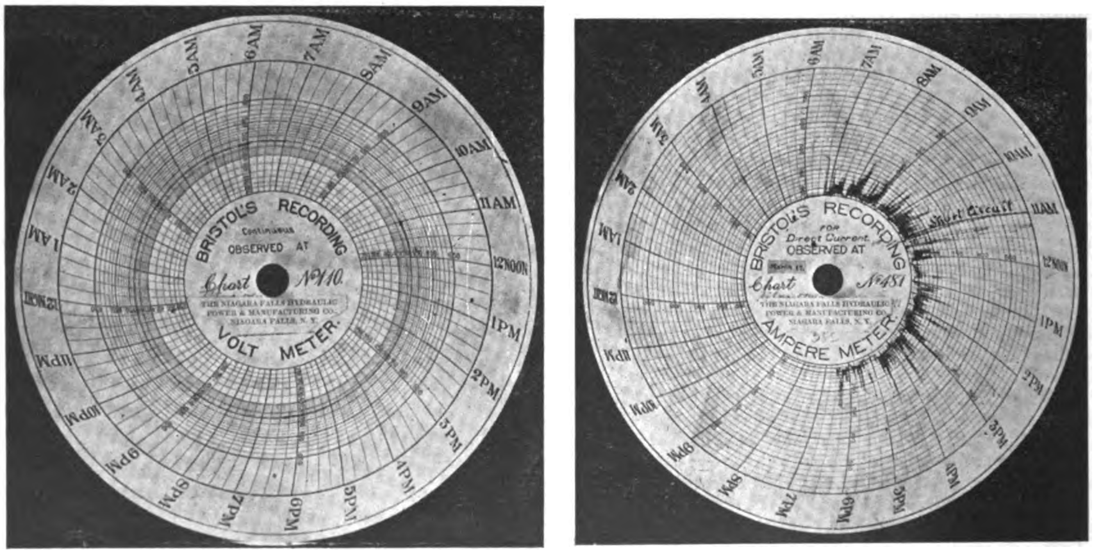
The Hardie Compressed Air Locomotive for the Elevated Railroad, New York.

We wish the experiment all success, but we are not seriously alarmed that the Manhattan Elevated Railway will adopt compressed air as its motive power.

A SHORT CIRCUIT ON THE NIAGARA GORGE ROAD.

BY ORRIN E. DUNLAP.

An incident occurred at Niagara Falls on March 17th last which goes a good way to show the high efficiency of one of the great power installations there. On that day while men were engaged in building the new steel arch bridge across the Niagara gorge, they let a large piece of steel fall into the gorge, and it dropped across the wires of the Gorge road, breaking them and causing a short circuit to exist for over half an hour. The current that supplies this road is furnished by the Niagara Falls Hydraulic Power and Manufacturing Company from their power house at the water's edge in the gorge, and is generated by two General Electric 750 horse-power machines operating at a potential of 500 volts, direct connected to a 2,000 horse-power turbine made by James Leffel & Company, of Springfield, Ohio, which is equipped with a governor made by the Lombard Water Wheel Governor Company, of Boston, Mass. The picture of the ampere meter chart in use at that time shows that the short circuit occurred close on to 11 a. m., its record being plainly discernible on the chart. The voltmeter chart of that day, also presented, shows how steadily the governor did its work at the time of the short circuit. It will be noticed that the recording line on the voltmeter chart is but a trifle heavier between the hours of 11 A. M. and 12 M. than it was all day, only the very slightest wavering being noticeable. Mr. F. G. Lott is the electrical superintendent of the plant, and he is delighted with the record made at such a trying time.



Record of a Short Circuit on the Gorge Road at Niagara Falls.

THE COST AND ADVANTAGE OF ELECTRICAL EQUIPMENT FOR RAILWAYS.—WITH AN ACTUAL EXAMPLE.

BY JOHN C. HENRY.

Some months ago I was strongly impressed with the broad gauge ideas emanating from Mr. Chauncey M. Depew, president of the New York Central Railroad Company, in regard to steam railway men and matters. He said they were living in a tunnel, and it was difficult for them to appreciate anything on the outside. I supposed from his language that the versatile gentleman who stands at the head of the highest order of steam railway development, was one of the exceptions, and that he was big enough to look at both sides, but a recent interview with him, an abstract of which appeared in some of the electrical papers recently, shows my mistake. He is reported to be looking for an electric motor that will transport passengers and freight cheaper than the steam locomotive. His condition reminds me forcibly of an incident I once heard about, of some poor, shipwrecked sailors who, with distress signals flying, were suffering for fresh water. On making known their wants to the officer of a vessel who had gone to their relief, he shouted back, "Drop your buckets, you are in the mouth of the Amazon."

Steam railway men have within convenient reach a force which is as irresistible as the Amazon at its mouth, but it is on the outside of their tunnel, and I fear our wee voice will never reach them without the assistance of The Electrical Engineer.

Railway men are not exempt from the old adage, "It is hard to teach an old dog new tricks." I am forcibly reminded of this in looking back over the early struggles in the trolley railway development. Street railway men fought very shy of the "new patented" transportation method. The historic roads, those built by Daft at Baltimore, by the writer at Kansas City, van Depoele at Appleton, Bentley and Knight at Allegheny, and Sprague at Richmond—all had grades on which it was impracticable to use animal power. Very little of the money to put those roads in operation was furnished by street railway men. With their success, however, the value of street railway franchises multiplied, and if the increased distance traveled, refinements added, and time saved, have measurable values, the expense of traveling on street railways has decreased in many localities not less than one thousand per cent., while that on steam railways, with their old methods has remained unchanged; in the face of these facts, is not the question of substituting electric motors for steam, a fitting subject for investigation by students in political economy, railway commissioners and legislatures?

A good deal has been written about "Electric Motors Under Steam Railway Conditions," but in the majority of cases the investigations have been carried along on well-known street railway lines, the investigators seeming to lack the dash and education in expedients which is so necessary in carrying out new problems.

Below I present the result of my investigation of what at first appeared to be a very difficult railway problem, i. e., the electrical equipment of the Florence & Cripple Creek Railway. If the work is carried out on the lines indicated, it will result in a saving over present earnings more than sufficient to pay desirable interest on the bonds and stock of the road; if any one will take the trouble to figure the same out on street railway or third-rail lines, they will probably find it to be a losing proposition.

Syl. T. Smith, Esq., President, Florence and Cripple Creek Railway.

Herewith I hand you some preliminary figures and information concerning the cost and advantages of an electrical equipment for your railway. They are based on the following data I have been provided with:

Distance, Florence to Cripple Creek, 40 miles.
Gauge, 3 feet.
Grades, Florence to Russell, 8 4-10 miles, 1¾ per cent.
Grades, Russell to Alta Vista, 23 miles, 4 per cent.
Grades, Alta Vista to Cripple Creek, 9 miles, level.

The road between Russell and Alta Vista has a great many 32 degree curves.

The present equipment consists of 12 steam locomotives, all of which are of the latest Baldwin pattern; cylinders 16 x 20, 8 wheel connected; drivers 36 inches; steam pressure 160 lbs.; weight, 73,000 lbs., without tenders; two of such locomotives are now required to haul 10 loaded cars, each weighing 37,000 lbs., complete, up the heaviest grades at a speed of 5 miles per hour.

In changing from steam to electric motors, assuming you are hauling the equivalent of 40 loads from Florence to Cripple Creek per day, together with your passenger trains, by using electric motors, the following expenses would be avoided:

Avoidable Expense per day:

8 Engineers at $4.68	$36.84	
8 Firemen at $2.78	22.24	
3 Engineers (Pass) at $4.68	14.04	
3 Firemen (Pass) at $2.78	8.34	$81.46
Coal on tender for 11 locomotives, 3½ tons each, at $2.75 per ton		125.62
3½ tons at $5 per ton, delivered on tenders at Cripple Creek		17.50
Expense of 6 water tanks, at $1.50 per day each		9.00
Attendance and repairs on 12 locomotives, including shop and roundhouse labor, superintendence and tools (material not included) at $6 per day		72.00
Total		$305.83

The Additional Expenses per day would be:

1 Electrician at $5	$5.00	
7 Motormen at $3	21.00	
1 Chief engineer at $100 per month	3.30	
2 Assistant engineers at $75	5.00	
2 Laborers (wipers) at $2	4.00	
Repairs and attendance on 7 motors at $1.20 (material not included)	8.00	
30 tons of coal under stationary boilers at $1	30.00	
Total new expense		$77.05
Saving with electrical equipment per day		$228.78

In addition to this, other savings of very considerable importance would be made, which are impossible to estimate.

The electric locomotive would have swivel trucks, with a wheel base of about 5½ feet, and would curve much easier than your locomotives on your many miles of 32 degree curves. The probabilities are that one-third of the power now absorbed by your locomotives with their 11 feet 9 inch driver wheel base, would be avoided, with a corresponding reduction in the wear and strain on the curved track.

As the weight of the electric would be very much less than the steam locomotives, the destructive effect of the track and the maintenance of way, would be more than correspondingly decreased. The rule is that this effect increases with the square of the weight (up to the elastic limit) which in your case is sometimes exceeded, as evidenced by bent rails, etc.

Another great saving would be effected in the rolling stock. Steam locomotives do their work by a succession of jerks, first on one side and then on the other. This effect is very pronounced on such roads as that up Pike's Peak; the tendency to rack and weaken the cars is much greater than where electric motors are used, as their strain upon the cars is without impulse or shock.

While your locomotives are doubtless the best steam ones that have been designed for severe mountain work, they are very inefficient machines, and there seems to be little chance to improve on them, as the manufacturers have already strained points in every direction to increase their force and efficiency. The boiler pressure, which is now 160 lbs., is really close to the danger line. The weight which is more than 50 tons, could not be increased without injury to the track. The leverage could not be increased by decreasing the size of the drivers, as they are now but 36 inches in diameter. The boiler could not be lengthened without increasing the wheel base, which your sharp curves would not permit. Notwithstanding all of this weight and strained engineering, the locomotives do not develop at the draw bar on your curves over 120 horse power at a speed of five miles per hour, cutting off at half stroke.

That most popular standard street railway motor known as G. E. 800, weighs about 1,600 pounds, with 33 inch wheels; at a speed of 11 miles per hour, it exerts a horizontal effort of 800 pounds, properly geared; it is consequently capable at a speed of 5 miles per hour of giving a draw bar pull about equal to its own weight.

I would propose in place of the steam locomotives to use electric locomotives of about double their capacity, so that one motor would handle 10 loads up to the 4 per cent. grades. After due consideration I have concluded the following installation would about fill the bill:

Although the equipment would be quite a departure from ordinary street railway practice, I am not straining any engineering possibilities, or proposing any plans which would not be approved by the best available talent, while they might be questioned by engineers of less experience. The steam power to generate the current would be located at the coal banks near Florence. The current would be transmitted to duplicate converters, located at the telegraph stations on the right of way along the railway, at a potential of 20,000 volts. Each standard direct current locomotive would have four 600-volt 100 horse power motors. The trolley wires would be supplied with direct current on the Henry three-wire commutative system (see U. S. Patent 545,158, of Aug. 27, 1895). One side would have a difference of potential of 800 volts, and the other of 1,200. The motors would receive current from either or both sides, i. e., at 800, 1,200 or 2,000 volts pressure, and be further regulated by connecting them in series or in parallel. In no case, however, would any one of the motors receive current at over 600 volts potential (this being the common trolley railway pressure). To prevent racing when the armatures are connected in series, the field magnets would be separately excited by being connected in series with a rheostat to the low voltage side. Owing to the high pressure on the mains and working conductors the losses would be less than on the ordinary street railway circuits. While the losses in regulating the motors would be about nihil at any speed up to the maximum, it is thought that these savings would more than compensate for the losses inherent in the transformers. The trolley wires and three-phase transmission wires would be carried on the same pole line. The method of suspension would be the combination diagonal span and bracket construction. (See The Electrical Engineer, March 31, 1897.)

The cost of the complete installation would be about as follows:

50 poles per mile, including brackets, insulators and setting at $5 each, total for 40 miles	$10,000	
For 3-phase current, 120 miles of No. 1, hard drawn insulated copper wire at 13c. per lb.; total	28,628	
For trolley circuit, 40 miles of 000 wire, and 40 miles No. 1	28,628	
Stringing wire and bonding track at $100 per mile	4,000	
Line construction complete		$71,256
7 locomotives at $6,000 each		42,000
4 400-k. w. dynamos, at $20 per k. w.		32,000
Converters		40,000
4 500-h.-p. stationary engines at $5,000		20,000

4 500-h.-p. water tube boilers, at $12 per h. p.	24,000
Electrical incidentals	5,000
Building power house and setting machinery	15,744
Total	$250,000

In figuring on the capacity of the machinery, we have aimed to have one of the 500-horse-power units in reserve; the balance would be quite sufficient to carry the maximum load. No estimate is made of the value of the 12 steam locomotives, which could be disposed of.

This electric plant could be used to advantage in operating the proposed Florence Southern road, without much additional expense, as current can be distributed from the central point with much less loss than from the ends of the line. Besides these there need be no additional expense for station attendance.

The distribution system could also be amplified and used to great advantage in furnishing the mining camps with light and power. It would not require, comparatively speaking, much more of an outlay to deliver 1,000 electrical horse power at the mines, which would doubtless sell at very high prices, where it could be used to operate pumps, hoisters, etc.

AN ELECTRIC ROAD FOR NICARAGUA.

A dispatch from Richmond, Ind., of May 26 says: Announcement was made here of the formation of a company to build a 150 mile electric railway line in Nicaragua. Isham Sedgwick, of this city, is president; Peter Baches, Trenton, N. J., secretary, and C. H. Hall, Trenton, N. J., treasurer. The nominal capital is $100,000 and the name of the company is the Atlantic and Lake Nicaragua Railroad and Navigation Company. The company gets numerous concessions from the Nicaragua Government, among which are 250,000 acres of land. There is only one short railroad in that country now.

ROENTGEN RAYS

THE DENNIS FLUOROMETER.

Experimenters in X-ray work will welcome the apparatus which has been perfected by Mr. John Dennis, of Rochester, N. Y., and which has been called the fluorometer.

Mr. Dennis was one of the earliest to recognize the characteristic distortion of the Röntgen shadow and set about devising an appliance which would make certain diagnosis of the presence of bullets, needles, calculi or other foreign objects which are more impermeable to the X-ray, than the tissue of the human organism.

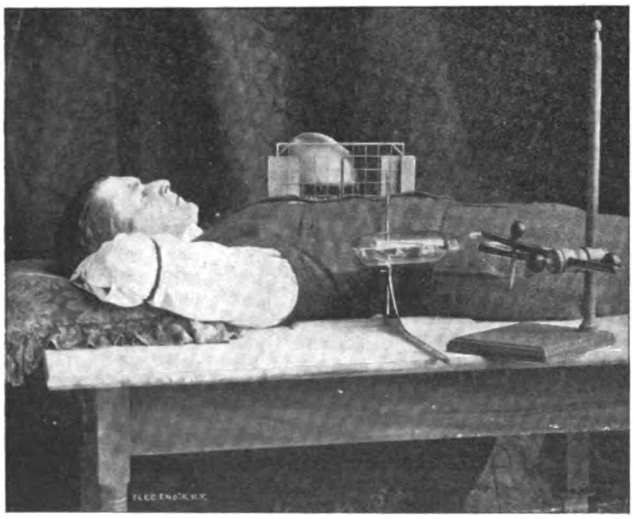


Fig. 1.—The Dennis Fluorometer—First Position.

Very early in the history of the X-rays it was realized that it could be made a very valuable adjunct to surgery. At the same time, however, there came the disappointing conclusion that no matter where a Röntgen ray picture apparently located a bullet, a needle or other foreign object in the human body, it was frequently not where it appeared to be.

Mr. Dennis' appliance establishes a definite cross section of the body by means of an angle piece which is impermeable to the rays. As will be seen by the accompanying engravings, the fluorometer is so constructed, as to fit any portion of the human body, neck, arm, limb or trunk, thus enabling the observer with the fluoroscope to determine the exact location of the foreign object.

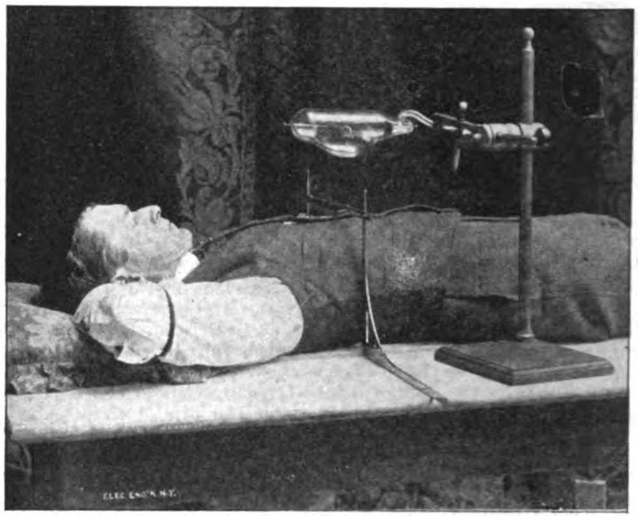

Fig. 2. The Dennis Fluorometer—Second Position.

It must be remembered that all that is produced by means of the Crookes tube is a shadow. The object of the fluorometer is to enable the surgeon to control this shadow and produce an accurate right angle by taking two views, the foreign object being located at the point of coincidence.

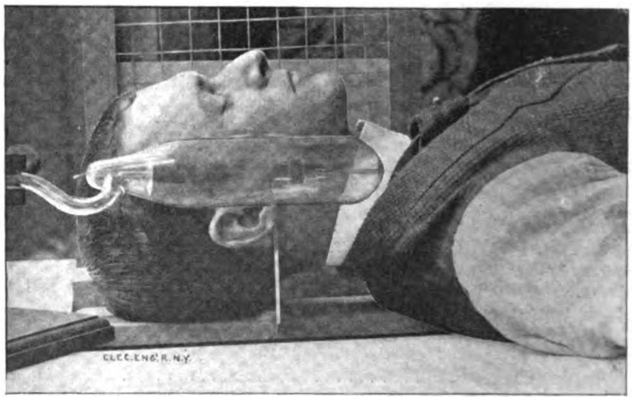

Fig. 3.—The Dennis Fluorometer as Applied to the Head.

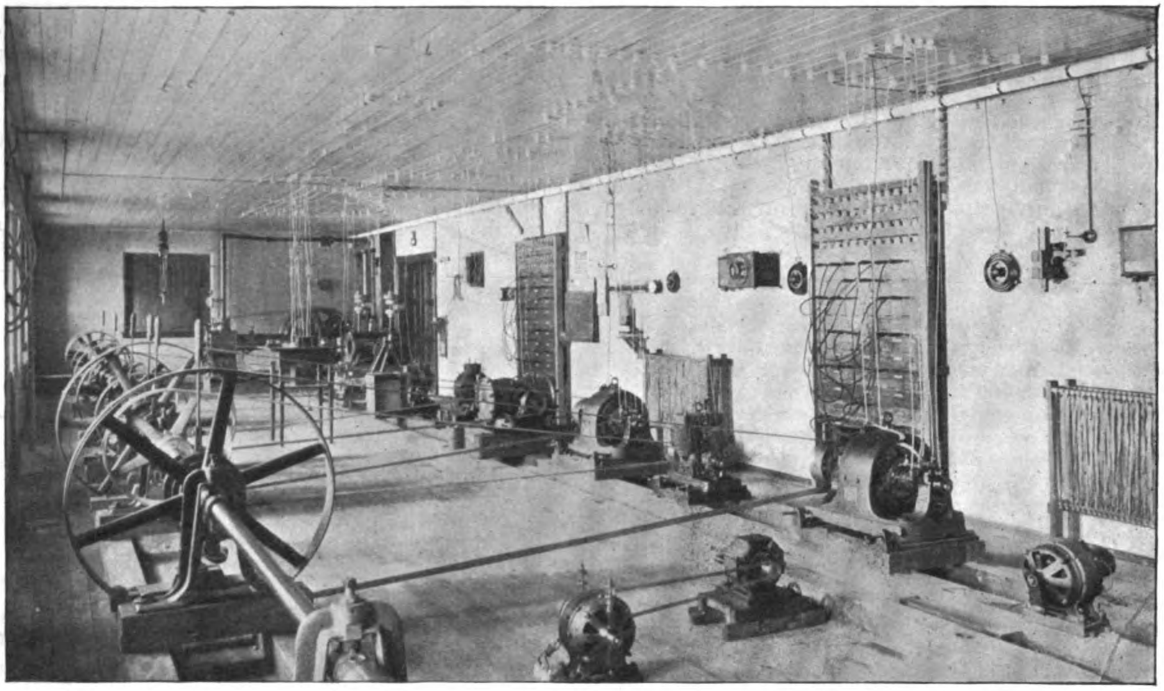
Early in his experiments Mr. Dennis discovered that the distortion in a Röntgen ray photograph was as one to thirteen in the distance of twenty inches; this distortion is corrected by the fluorometer. Incidentally the fluorometer demonstrates that the source of the energy is at the center of the platinum plate, which forms the anode of the tube, as will be seen by the engravings. The fluorometric appliance is brought within the parallelism of the rays, until it shows a single characteristic straight line on the field of the fluoroscope. By means of what may be called sights, a cross section of the subject is brought absolutely in line with the foreign object under observation, with the result that a second view by use of the sights discloses the exact location without the necessity of a long exposure required for the taking of a picture.

By means of a simple adjustable table, as shown in the engravings, Mr. Dennis controls the character of the Röntgen shadow. The table is provided with an aperture by means of which the second view is taken from below, the same as from the side. The metallic grating enables the observer to measure the distance from the base line to the foreign object at a glance, the meshes of the grating being exactly one inch apart.

ELECTRICAL ENGINEERING AT LEHIGH UNIVERSITY.

At the Lehigh University electrical engineering and physical science are taught in the physical laboratory, erected in 1893. The building is of stone, 235 feet long, 44 feet wide, and four stories in height. The two lower floors are devoted to electrical engineering. On the west side of the first floor is the dynamo laboratory, comprising dynamo room, store room, workshop, battery, computation and cloak rooms, etc. The dynamo room is 70 feet long and 20 feet wide. A 50-horse-power Straight-Line steam engine drives a ground line shaft, to which the several dynamos are connected by belts and clutch pulleys.



Dynamo Laboratory, Lehigh University, Bethlehem, Pa.

Electrical Laboratory, Lehigh University, Bethlehem, Pa.

The electrical plant consists of two Westinghouse rotary transformers, two Edison dynamos, Thomson-Houston arc dynamo, Richter arc dynamo, Wenstrom incandescent dynamo, Westinghouse alternator, two Tesla induction motors, several small motors, ten alternating-current transformers, etc. The laboratory is supplied with ammeters, voltmeters and wattmeters of various types, Kelvin balances, Brackett cradle dynamometer, standards of capacity, etc. The battery room contains an 80-cell Chloride accumulator, which supplies current for experimental or testing purposes at times when the engine is not running. By means of switchboards located in the battery and dynamo rooms, current is made available for use in any of the laboratories or lecture rooms throughout the building.

On the east side of the first floor is the Thesis Laboratory, comprising eight separate rooms of uniform size, office, balance room, and constant temperature vault underneath. Each of the separate rooms is furnished with three stone tables resting on foundation piers; one is specially fitted up for arc light photometry; in all the use of iron has been avoided in order to make them suitable for magnetic measurements. The room underneath is similarly furnished, and is specially suitable for accurate measurements of resistance.

On the west side of the second floor are the designing room, blue printing room, offices, reading room and apparatus rooms. The designing room, 56 feet long by 44 feet wide, provides ample accommodation for designing and draughting. It is well lighted and contains the beginnings of an electrical museum. The reading room contains a collection of works of reference, and sets of several electrical journals. On the table will be found the current numbers of the leading electrical journals.

On the east side of the second floor are the laboratory of electrical measurements, magnetic room, office, comparator room, store room, etc. The electrical laboratory, 60 feet long by 44 feet wide, provides desks with drawers and lockers for eighty students. Like the Thesis laboratory below, it is entirely free from iron, the gas and heating pipes being made of brass. Slate shelves fastened to the walls provide suitable support for delicate instruments. A selection of the best books on electrical measurements is kept at hand, and references are given to such of these as treat a particular problem in the best manner. The laboratory is well supplied with sets of the more common instruments, and recently a number of instruments have been added comprising Anthony form of Wheatstone bridge, megohm resistance box, Crompton potentiometer, Ryan electrometer, standard condenser, Weston ammeters and voltmeters etc. The magnetic room has been fitted up and set apart for measurements of the magnetic qualities of iron and steel.

During the past two years the course in electrical engineering has received great development under the direction of Dr. Alexander Macfarlane.

MEXICO.—J. A. Carrigan of New York, John H. Foy and Michael O'Boyle, of Pittston; George E. Giles and G. P. Rogers, of Carbondale, Pa., by the trip in Mexico expect to secure contracts from the city of Pueblo aggregating $6,000,000. The work will consist of laying twenty-five miles of electric railroad, putting down 300,000 square yards of asphalt pavement, sewering the city and putting in a public water works.

ELECTRIC LIGHTING

MOORE VACUUM TUBE LIGHTING PROGRESS.

At the invitation of the Moore Electrical Company a party of about seventy-five ladies and gentlemen gathered at the Moore laboratory, at Newark, N. J., to witness the latest results obtained by Mr. D. McFarlan Moore with his system of vacuum tube lighting.

The room in which the demonstration took place was 10 by 25 feet in area, and was lighted by fourteen tubes, placed close under the ceiling in the position occupied by a picture molding in an ordinary room. These tubes were 7 feet 6 inches long and 2½ inches in diameter, and were in fact the same tubes used by Mr. Moore last year, at the Electrical Exhibition, in this city.

In a short address by Mr. E. J. Wessels, president of the company, it was pointed out that the great improvement made by Mr. Moore on his work of twelve months ago lay in the substitution of a rotary current interrupter in place of a vibrating interrupter. With the vibrating interrupter it will be recalled, only 6,000 breaks per minute could be obtained, whereas with the present rotator 50,000 breaks per minute are easily attainable. The effect of this increased rate of vibration was very marked in the great steadiness and evenness of tone of the light emitted by the tubes. An improvement of equal importance to the substitution of the rotator for the vibrator, is, that by the use of the rotator practically any number of tubes can be operated together, whereas formerly as many vibrators were required as there were tubes. Of course this means an enormous reduction in the amount of apparatus and current necessary to operate the system.

ELEC. ENG'R. N.Y.

Picture Taken by Moore Vacuum Tube Light at Newark, May 27, 1897.

The Moore system therefore at present is in practically the same condition, so far as working and general distribution are concerned, as ordinary incandescent lighting, i. e., it is run on the multiple arc system, in which any number of lamps can be run connected across two wires.

Another fact of paramount importance consequent upon the use of a high number of breaks in the rotator is that the power consumed for lighting a given number of tubes is greatly reduced. Indeed, according to Mr. Moore, the power now required is only one-half as much as that previously required with the vibrators.

The new rotator consists of a revolving switch or commutator upon which bear a series of brushes. The segments are placed on the periphery of a revolving cylinder which, with the brushes, etc., are enclosed in a vacuum tube about 12 inches long and 3 inches in diameter, which also contains the armature of the motor that drives the switch cylinder. The field magnets which influence the armature are placed outside of the vacuum tube.

The current for lighting the tubes was taken from a very unsteady 220-volt street circuit.

Mr. Moore also showed a number of very interesting experiments illustrating the use of the light in decorative work. Among these was shown "The Candlestick of the Future," consisting of a glass tube six feet high, carried in a candlestick of corresponding proportion. This tube was lighted up by induction, having no connection with any wires whatever. A photograph of those present was taken by the light of the tubes, and is here reproduced. Mr. Moore also showed that he had worked out some of the practical details of his system by placing a push button on the wall, by which the tubes could be lit and extinguished.

The walls of the room were hung with a number of vacuum tube advertising signs, which showed the possibilities which lie in this direction. All present expressed themselves as highly pleased with what they had seen.

LIGHTING INSTALLATION IN THE KINGSTON, N. Y. CEMENT QUARRIES.

An interesting electrical installation has recently been made in the quarries and mills of the F. O. Norton Cement Company, at Binnewater, N. Y., situated in the Rosendale cement district about seven miles from Kingston. This company manufactures the natural cement as distinguished from the Portland, the bulk of the latter consumed here being imported from Europe. The deposit from which the Norton (natural) cement is made is bluish gray magnesian limestone or cement rock found in strata of between fourteen and seventeen feet in thickness, constituting the hills along the valley of the Roundout Creek. The process of manufacture consists in quarrying the stone in the ordinary manner with powder and dynamite. From 120 to 125 tons of cement rock is disengaged at each blast. The average result is about 4½ barrels of cement to one ton of rock.

The stone as taken from the quarries is broken up into pieces of about a cubic foot each, and laid upon small cars. The cars are then hauled to the kilns which are cylindrical structures built of stone. These are about nine feet in diameter and twenty-eight to thirty feet in height, the sides converging at the bottom. In these kilns layers of stone about 6 to 10 inches are placed each alternating with a layer of pea coal. The stone is then thoroughly burnt to remove the carbonic acid gas and the calcined produce is drawn from the bottom of the kilns twice every 24 hours. After careful inspection, the over burnt and under burnt stones are separated and the properly burnt product is wheeled to the cars and carried to the crushers, which reduce it to a suitable size for grinding. From these it passes to the mills immediately underneath, where it is reduced to powder and is conveyed by machinery to another portion of the mills, where it is fed into barrels lined with paper to exclude dampness.

At the quarries about sixteen hundred barrels of cement are manufactured per day, running 300 pounds to the barrel. The galleries have 50 feet face. The veins are known as the dark vein 17 feet in thickness and the light vein about 14 feet in thickness. The two qualities of stone are mixed in a stone crusher producing a uniform grade of cement. The galleries are upheld by pillars 20 feet square and 30 feet apart.

The power plant consists of four horizontal steel tubular boilers, 16 feet by 17 feet, furnishing steam at 100 pounds pressure to a 750-horse-power Harris-Corliss cross-compound slow speed engine. This power is used to operate sixteen cracker mills, the crushers, etc., etc.

The electric plant consists of a 30-kilowatt alternating current incandescent dynamo, manufactured by the General Electric Company, as, in fact, are the lamps and wiring devices of which the plant consists. This machine is driven by a 10 x 12 horizontal automatic Ball engine. There are now installed 103 incandescent lights, lighting the kilns shed, where the calcined product is taken to the crushers, the mills, the packing rooms, the shipping rooms and various other departments of the factory.

The quarries are lighted by 40 incandescent lamps and 14 arc lamps. The current is used at a pressure of 300 volts, being reduced by transformers to the necessary voltage for arc and incandescent lamps. Each arc lamp is operated by its individual transformers. In addition one or two incandescent lamps on flexible cords, protected by wire cages will be operated from the same transformer where particularly close light is required. Arc lamps are also connected by flexible cord to the transformers, which are placed back of the nearest pillar to the face of the gallery. The lamps are supported from the roof of the gallery by means of rope and pulley and give a most satisfactory general illumination for the whole work. The men have suspended a light for handling the drills and shoveling the broken stone in the loaded cars, etc., etc. Incandescent lights fixed in position are placed at the main platforms, turn table, etc., etc., while lamps for the purpose of general illumination are also placed at moderate intervals along the galleries now being operated. When the blasts are fired, the lamps are unhooked and taken behind the pillars.

The above installation has entirely done away with oil lamps the use of which in many cases rendered work almost impossible, it being necessary to place the drills at the very top of the gallery on a shelf sufficiently below for the erection of the drill. In the days of oil lamps the room was so filled with smoke and fumes that the men could only work there for a short time; in fact, the whole mine was rendered murky and disagreeable to work in by the odor from the lamps.

The circuits are carried into the quarries from the power house, a distance of about 400 feet in one direction and 1,500 feet in the other. They are carried along the galleries fastened to insulators fixed to plugs driven into holes in the roof of the worked-out galleries. From various points main loops are carried to the galleries where the work is going on.

According to the manager and engineer, no considerable difference can be detected in the amount of coal used since the introduction of electricity, and they are fully satisfied that it costs no more than they were obliged to pay each month for oil under the old method. They are equally certain that the amount of work which can be done by means of electric illumination is greater while far more easily performed. The present electric plant is only working to about one-half its capacity and lights will be added as the work is extended.

THE GROWING BURDEN OF MUNICIPAL DEBTS.

The following is taken from the St. Louis Globe-Democrat: "The Greater New York will begin business as a municipality, so to speak, on January 1, 1898, with a municipal debt in excess of $200,000,000, a debt larger, according to the New York Sun, than that of any four other cities of the country. There is a general opinion, for which, however, there is no real warrant, that the debt of American municipalities is based upon their population, area, age and resources; but the fact is that while these elements regulate the running expenses of American cities, the debt is fixed rather by the form of government they have enjoyed or suffered from in the past. Boston and St. Louis are cities of the same size nearly (the difference in population between the two was less than 3,000 by the last census), yet the municipal debt of Boston is three times greater than that of St. Louis, while, on the other hand, the tax rate in St. Louis is 50 per cent. greater per $1,000 of valuation than it is in Boston. Louisville, a city of 200,000 population, has a debt of nearly $9,000,000, but Covington, in the same State, with a population of 37,000, by the last census, has a debt of $2,400,000, and Newport, Ky., a city of 24,000, has a debt of $1,100,000. Chicago, which has a population considerably in excess of 1,250,000, has a municipal debt of $17,000,000, whereas New Orleans, which has a population of 250,000, one-fifth of Chicago, has a debt of $15,000,000, and some local improvements under way will materially increase it. Indianapolis, with a population at the last census of more than 100,000, has a debt of $1,108,000, whereas, Evansville, which by the last federal census had a population of only 50,000, half as large, has a debt of $2,100,000. The municipal debt of Kansas City is $4,000,000 and Sioux City, Ia., owes $1,200,000. The municipal debt of Philadelphia is $2,000,000, and of Pittsburg $12,000,000, but Providence, which has about one-half the population of Pittsburg, has a municipal debt of $13,250,000. Milwaukee and Detroit are two cities having almost the same population—205,000 by the census of 1890. Since then Detroit has increased more rapidly in population, and the area included in it is somewhat larger than is the area of Wisconsin City. Yet the debt of Detroit is $4,800,000, whereas, the debt of Milwaukee is $6,200,000. San Antonio, Texas, an ancient town of less than 40,000 persons, has been wide awake enough to contract a municipal debt considerably in excess of $2,000,000, whereas the city of Fort Worth, which has been generally alluded to as being a thriving and enterprising settlement, has a debt of $1,300,000 only. In New York State, Buffalo has a bonded debt of $12,000,000, Syracuse of $5,800,000, Troy of $1,200,000 only, Long Island City of $3,500,000, Yonkers of $3,000,000, Albany of $4,100,000, Rochester of $8,400,000, Utica of $360,000, Poughkeepsie of $1,700,000, Dunkirk of $275,000, and Mount Vernon, N. Y., of $800,000.

VOL. XXIII. NEW YORK, JUNE 2, 1897. No. 474.

VERTICAL ENGINES IN CENTRAL STATIONS.

THE advantages of direct connection for dynamos are such that this method of driving may now be considered the standard. Where the space available permits of it, modern practice, as a rule, calls for the installation of horizontal engines, but where land is valuable the vertical engine has come to be the only alternative. In the design of vertical engines for direct connection in such plants, marine engine practice has been very closely followed with such modification of details, of course, as the differing nature of the two kinds of work have dictated. But in every case the general type of construction with the cylinders standing above the driving shaft has been retained without exception, so far as we are aware. But is it safe to assert that this type of vertical engine will continue to hold undisputed supremacy? Already we note tendency to change, brought about by the experience had in the past few years. In the opinion of at least one well-known engineer, there are distinct gains afforded by not having the cylinders and steam work and oiled surfaces above the generator. In support of this contention, it is pointed out, first, that none of the electrical manufacturing companies will guarantee the insulation of their armatures if the latter are subjected to oil soaking; yet it is almost impossible by any method of screening to prevent oil being drawn into the machine. All vertical engines of the type now generally in vogue have their steam cylinders arranged above the armatures, and possess oiling devices and exposed oiled surfaces that cause a continuous spraying of oil, as any one familiar with this type of engine must be aware. By reversing the relative positions of steam cylinder and generator, several distinct advantages are claimed to be obtained. In the first place, by lowering the steam plant, the pistons receive a greater pressure when they most need it, that is, when working on the up-stroke against gravity. With the present arrangement, just the reverse is the case, due to the reduced area of the crank end piston area, caused by the piston rod, and when one considers that the pistons, rods, and other dependent devices, may, and often do, weigh several tons in large engines, this loss of pressure is by no means a negligible quantity. But the most important feature is, that it brings all oiling devices and oiled surfaces well below the armature and all steam connections below the dynamo, virtually separating the station into a steam and an electrical section, or rather level. This arrangement is also claimed to allow of more compact construction, as the armatures can be readily removed from the bearings of the engine with the shaft and crank, which could be interchangeable for the different engines of the same size. It is maintained that by adopting an arrangement such as that outlined above, the rate of depreciation of generators in central stations which is now calculated at from 10 to 12 per cent., can be reduced to from 4 to 6 per cent. That this plan of engine and dynamo arrangement for central stations is not purely speculative, is shown by the fact that designs for such a construction are now actually being made which will shortly be in the hands of the engine builder.

THIRD RAIL PROGRESS.

THE third-rail system of electric railroading, which was first tried in actual practice by Daft fifteen years ago, has again come to the front and, if all signs are not misleading, will maintain its position as the method, par excellence, for converting steam roads into electric. The most recent conversion of this kind, that of the Berlin Branch, of the New York, New Haven and Hartford Railroad, has set the managers of other roads thinking, and dubious rumors are heard to the effect that the Erie and Long Island roads are contemplating similar changes. While every attempt of this kind is deserving of all encouragement, it is in no spirit of disparagement that we venture to raise the question, once again, whether the third rail as at present employed, namely fully exposed, will be found to answer all the requirements of American railway traffic. Where, as in the majority of roads in Europe, there are no grade crossings, and where, in addition, the entire track is fenced or hedged in so as to shut out all trespassing of man or beast, an exposed third rail offers no difficulties; but where an unprotected track is the rule, as in America, experience will show that some methods must be adopted to avoid annoying, and possibly serious, consequences. We are led to these reflections by a perusal of the accounts of the daily and frequent accidents on the new third rail electric branch of the New York, New Haven and Hartford Railroad, which have reached us ever since the opening of the road. Now, it is a carpenter disabled by his hammer coming in contact with the rail; next the dropping of a brake bar from a freight car causes a short circuit, which results in a damaging burnt-out at the station; and again a girl is shocked, horses are disabled and dogs killed. Indeed, only last week one of the members of the American Society of Mechanical Engineers, who had been invited on an inspection run over the new road, saw his steel-stemmed umbrella go up in a blinding flash of light. Luckily no human lives have yet been lost, but there is no telling when a combination of circumstances may bring about such a result. That such a condition of affairs can continue indefinitely in a thickly populated district, or wherever animals are apt to stray on the track, is hardly probable, and it is greatly to be hoped that those in authority in the New Haven road will give this matter their serious attention, not only for their own sake, but for the effect which a continuance of these mishaps will have on the adoption of the third rail by other roads. The problem of protecting the third rail from accidental contact is comparatively simple, and we could, in fact, point to more than one method which, it seems to us, would answer all the requirements of practice. But after all, the mishaps above quoted are of the class of children's diseases. All new ideas of far-reaching importance must pass through perils not fatal, before reaching their full maturity, and, far from being disappointing, the results already accomplished are enough, in our estimation, to set at rest all questions as to the adaptability of the third rail for railway traffic, the belated and timid New York Manhattan Elevated Railway to the contrary notwithstanding.

"NIAGARA FOR BOILER FEEDING."

THE above whimsical topic was assigned at the Institute dinner the other night to Dr. Charles E. Emery, the engineering expert, whose familiarity with questions of power is regarded as enabling him to find, as he did, some new way of looking at Niagara. He certainly did not disappoint his auditors. In responding he said that he did not at first think he could treat the toast seriously, as the conception apparently led to such enormous and preposterous figures. The subject, however, was not one calculated to suggest merely a humorous reply, so finally calculations were made along the lines possible and revealed some relations of an interesting character. With 150 feet fall, which can be obtained with the canal, though not utilized in connection with the tunnel, one hydraulic horse-power requires 33,000 ÷ 150 = 220 pounds of water per minute, or about 440 pounds per electrical horse-power delivered at a distance. With a compound steam engine requiring 16 pounds of water evaporated into steam per horse-power hour, Niagara would furnish feed water for steam power for 60 x 27½ times as many horse-power as if the weight and fall of the water were utilized. Such power would not, however, be developed in a non-condensing engine, but in a condensing engine requiring condensing water. In such case there would be used on the average about 27½ times as much water for condensing purposes as for feed water, or 440 pounds per hour, the same as would be required per minute to develop one electrical horse-power at the end of a long electric line. In other words, the water required to generate 100,000 electric horse-power with water power at a distance having 150 feet fall is practically the same per minute as would be required by a compound condensing engine per hour to develop the same power.

Dr. Emery called attention also to the many interesting problems in connection with the hydraulic development of Niagara. The power must be sold in competition with steam power and supplied at Buffalo, where coal can be brought for about ½ cent per ton per mile or only $1 per ton for 200 miles transported. Such coal can doubtless be loaded into the cars for about 40 cents per ton so that it should be sold in Buffalo for about $1.50 per ton in large quantities. Under such circumstances water power transmitted as electrical energy can only compete with steam power by reason of the great amount of power developed which reduces the unit cost in a surprising degree. The cost per horse-power delivered is, of course, materially increased by the expense of transmission. Still the water power can compete with steam power where the high tension lines can be run direct to the exact locations where the power is utilized. He had not been able, however, to satisfy himself that the development of Niagara would greatly cheapen power in small quantities distributed at different points about Buffalo and the vicinity, for the reason that naturally the transmitted power would be supplied to stations already delivering power in small quantities which had to pay interest on a capital very much in excess of that required to generate and transmit the water power, a condition which would prevent important reductions in the cost of power to the smaller consumers. Dr. Emery's points are always well made, and it will be interesting to see how his conclusions work out in results.

THE BENEFICENT TROLLEY.

At a recent meeting of supervisors in convention at Los Angeles, Cal., Mr. John Mitchell bore strong testimony to the influence exerted out on the Pacific Slope by the trolley in enabling people to live comfortably in their own homes in handsome suburbs adjacent to the large cities. This phenomenon is evidently not restricted to any locality in this country, and should be observed presently in Europe, if a flat rate of fare is adopted that invites to the full trip and does not discriminate against the suburbs by increasing the fare for every mile. "Between the City of Oakland and the City of San Leandro," said Mr. Mitchell, "some eight miles, a stranger would suppose he was passing through a New England town, so thickly has it become settled. One great benefit has been that it has enabled poor men who were unable to have their homes in the city, owing to the high price of real estate, to locate outside the incorporated cities, by reason of rapid transit and convenience afforded by electric car systems, buy lots, build little homes and yet reach their places of employment in Oakland and San Francisco without difficulty." Mr. Mitchell mentions an increase of about a million dollars in the assessments of two townships in about two years, due to the electric lines, and he adds that between given points travel has been four times as great as it was when the community had to depend on steam railroads.

A LARGE RAILWAY ORDER ABROAD.

It must be a matter of gratification to all American electrical engineers that a large contract for electric railway apparatus has come to this country from England. The General Electric Company last week took an order from the London Central Underground road for $500,000 of railway motors, etc., and will proceed at once to fill the contract. It is true, this is not the first order to reach this country from Europe, as we have lately noted other sales by American electrical manufacturers, but it is by far the largest we know of. We hope soon to see such an order repeated. Last year, no less than 25 per cent. of American exports was of manufactured goods, and we believe that the growing export of electrical apparatus will soon raise the figures to an even higher point unless by extremely high protective tariffs we nip such trade in the bud by making the cost of production too great. Incidentally we are glad to learn that the firm of Morris, Tasker Company have secured an order for 38 miles of poles. American cars are also going into England, on their merits, as the recent discussion in the House of Commons proved very conclusively.

MUNICIPAL LIGHTING FIZZLE AT ALEXANDRIA, VA.

From a report of the recent meeting of the city authorities of Alexandria, Va., we gather that the city electric lighting plant and gas works are now running behind, and that the electrical service alone shows a loss of $1,000 per annum. The plant was put in with the usual hurrah and promise of the millennium, but to-day the authorities have been driven to consider plans for taking light even for the streets, from a private company. It is said that many members of the council favor selling both the electric light plant and the gas works, so that the city would get for $2,000 a year what is now costing it nearly $8,000. Not alone is there a financial difficulty, but the citizens complain of the inadequacy of the service. "Many times have the citizens wanted incandescent lights for their houses and places of business, but the city has never been able to furnish them, and, it seems, never will with the present facilities." In the interests of economy and better lighting, we trust that the city will soon sell out.

MOORE'S VACUUM TUBE LIGHTING.

Although very little has been chronicled regarding the work of Mr. D. McFarlan Moore since his unique demonstration of vacuum tube lighting at the Electrical Exhibition last May, that inventor has not been idle by any means. He proved this by the demonstration made last week, an account of which appears on another page. The substitution of a rotary interrupter instead of a vibrator has unquestionably brought with it a most marked improvement both in the efficiency and the quality of light produced in Mr. Moore's tubes, and after witnessing a continuous run of these lamps for over an hour, and noting the ease of control, we have no hesitation in saying that the Moore system is now in at least as good, practical, commercial shape as the Edison incandescent system was in 1880. With the further improvements which time and experience will indicate, the Moore system will surely make a place for itself, and a prominent one at that.

TELEPHONE OPPOSITION.

In another part of this issue is given a report of the meeting of independent telephone interests held at Chicago last week. It will be seen that the practical outcome for the present is a decision to hold a national telephone convention at Detroit on June 22. If organized opposition is ever to amount to anything that convention should be a critical point in its history. It will be noted from our columns this week that separate bodies have been meeting in different parts of the country. This is a sure way to encounter defeat especially in face of an enemy so splendidly equipped and so admirably trained and led as are the Bell forces. Jealousy of the promoter of the Chicago meeting is said to have kept other interests away from it, but it must certainly be recognized that if organized independent telephony is to carry any weight and exercise any influence with the public, it must be united, harmonious and aggressive.

It is interesting to note that there is an ordinance of the city of Salem, Mass., requiring that no pole erected on the streets shall be of any other wood than hard pine, finished square. The experience of the Salem Electric Light Company with poles of this kind has demonstrated to their satisfaction that hard pine is not suitable, and they have therefore petitioned the city council for leave to replace their present hard pine poles with either cedar or chestnut, whenever and whereever desirable in their view.

Complaints about poor telephone service must go for naught in view of the recent order issued, that all presents sent in for the young ladies in the New York telephone exchanges shall be returned. Presents have been coming in such quantities that the management decided to put a stop to it. The inference is obvious and palpable. No mere sentimentality or a bidding for attention would prompt to such wholesale generosity. The girls have evidently won these favors by their good work, which, of course, reflects credit upon the exchanges.

Mr. J. C. Henry, a veteran electric railway man, whose pioneer work is well remembered, furnishes us this week from his Colorado seclusion some remarkably interesting data embodied in his estimate for operating electrically the Florence and Cripple Creek Railway. Mr. Henry, it is evident, believes in the ability of electric locomotives to deal with most of the difficulties; and note will be taken of the fact that he figures on the basis of overhead trolley methods.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—XII.

STORAGE BATTERIES IN EDISON STATIONS.—Continued.

BY JOSEPH APPLETON. (Copyright, 1897.)

THE second battery plant is located at the company's First Station and is the largest of the four, it consisting of 144 cells of the Tudor type and having a capacity of 6,600 amperes for one and one-quarter hours, 3,432 amperes for three hours, 1,388 amperes for ten hours.

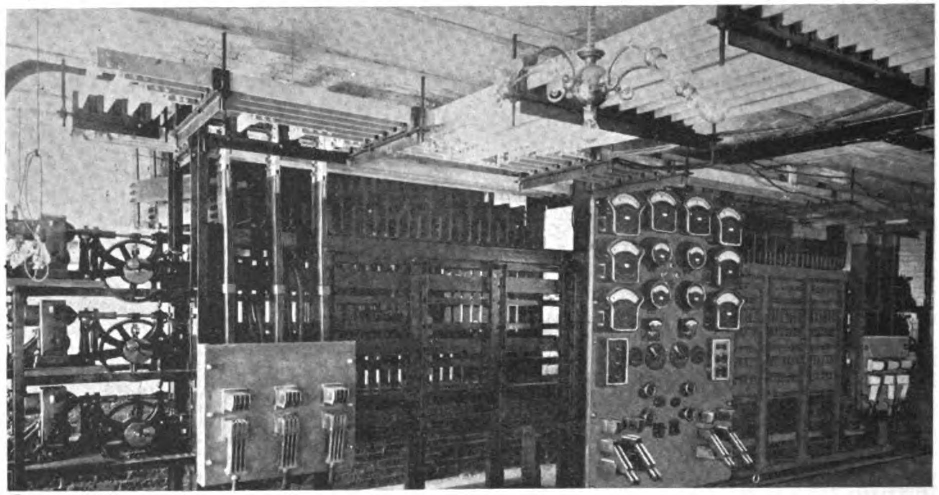

FIG 41.—STORAGE BATTERY SWITCHBOARD, FIRST DISTRICT STATION, EDISON ELECTRIC ILLUMINATING CO., BOSTON.

This plant is illustrated in Figs. 41 and 42, which show, respectively, the battery, switchboard and boosters user for charging. In this station there are three sets of busses, the switchboard being arranged accordingly.

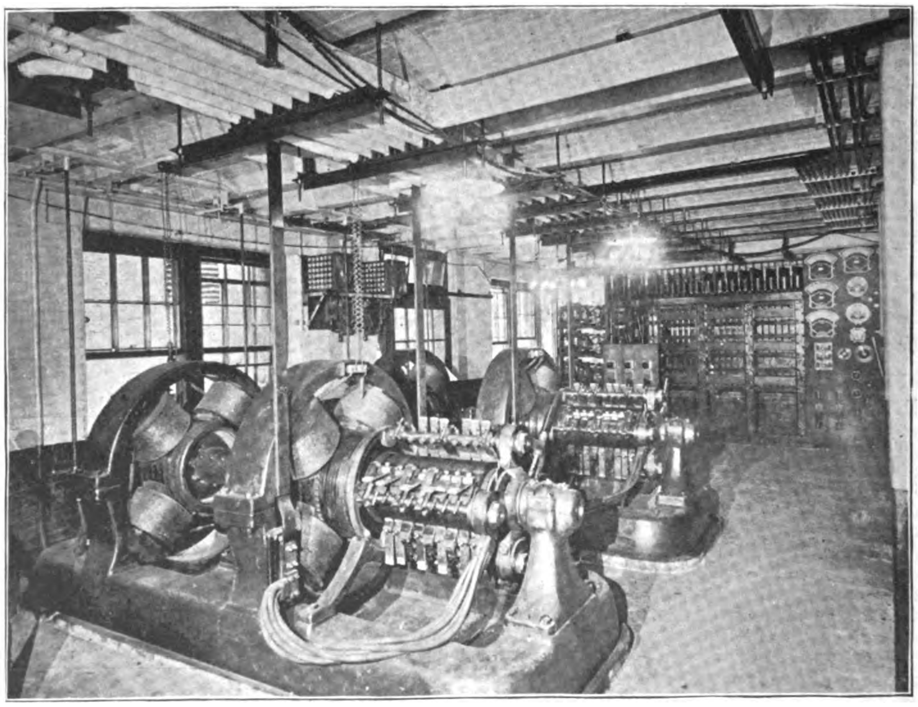

FIG. 42.—BOOSTERS AT FIRST DISTRICT STATION, BOSTON EDISON CO.

At the time this plant was installed it was the largest individual storage battery which had ever been erected, the cells being of much greater size than those in any European installation.

The installation of these two plants was the turning point in the history of storage batteries in this country, proving that the conditions of American central station practice did not differ sufficiently from the European methods to render the use of storage batteries less advisable and advantageous, as was frequently supposed, this being one reason given for the backwardness of American engineers in adopting them.

The third storage battery plant installed by the Boston Edison Company marked a fresh departure in direct current distribution in America, viz., the use of sub-stations consisting entirely of batteries, no generating machinery being employed. The problem arose of supplying a fashionable residential district, two miles from the nearest generating station, where it was impossible to erect a steam plant, apart from the question of poor economy which such a plant would give. The company had been compelled to refuse the supply of light and power in this district for several years on account of the fluctuation due to the great distance from the generating plant.

It was considered too great a distance to run new feeders of sufficient capacity to give good service and after careful consideration a storage battery sub-station was decided upon as giving the following advantages: New customers could be taken at the extreme end of their system, thereby extending the area over which they could supply current. Current could be taken from their most economical generating station on the water front, for charging the battery, at a time when the load was light, thereby increasing the economy of that station.

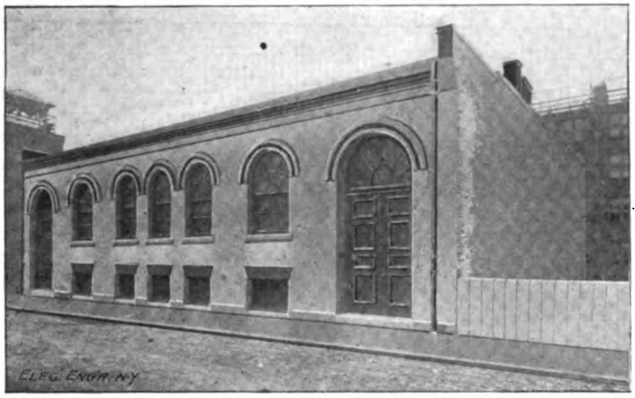

FIG. 43.—STORAGE BATTERY, SUB-STATION BOSTON EDISON CO.

The battery consists of 140 cells having a total capacity of 3,000 amperes for one hour, 1,500 amperes for three hours, 800 amperes for seven and one-half hours.

Figs. 43, 44, 45, 46 and 47 illustrate this plant, showing respectively the building, the interior of battery room, the switchboard arrangements and a still for providing distilled water for use in the battery.

The fourth battery now being installed by this company will be an auxiliary to their Second Station, which has a complete generating plant. The capacity of this battery is 4,000 amperes for one hour, 2,000 amperes for three hours, 800 amperes for ten hours.

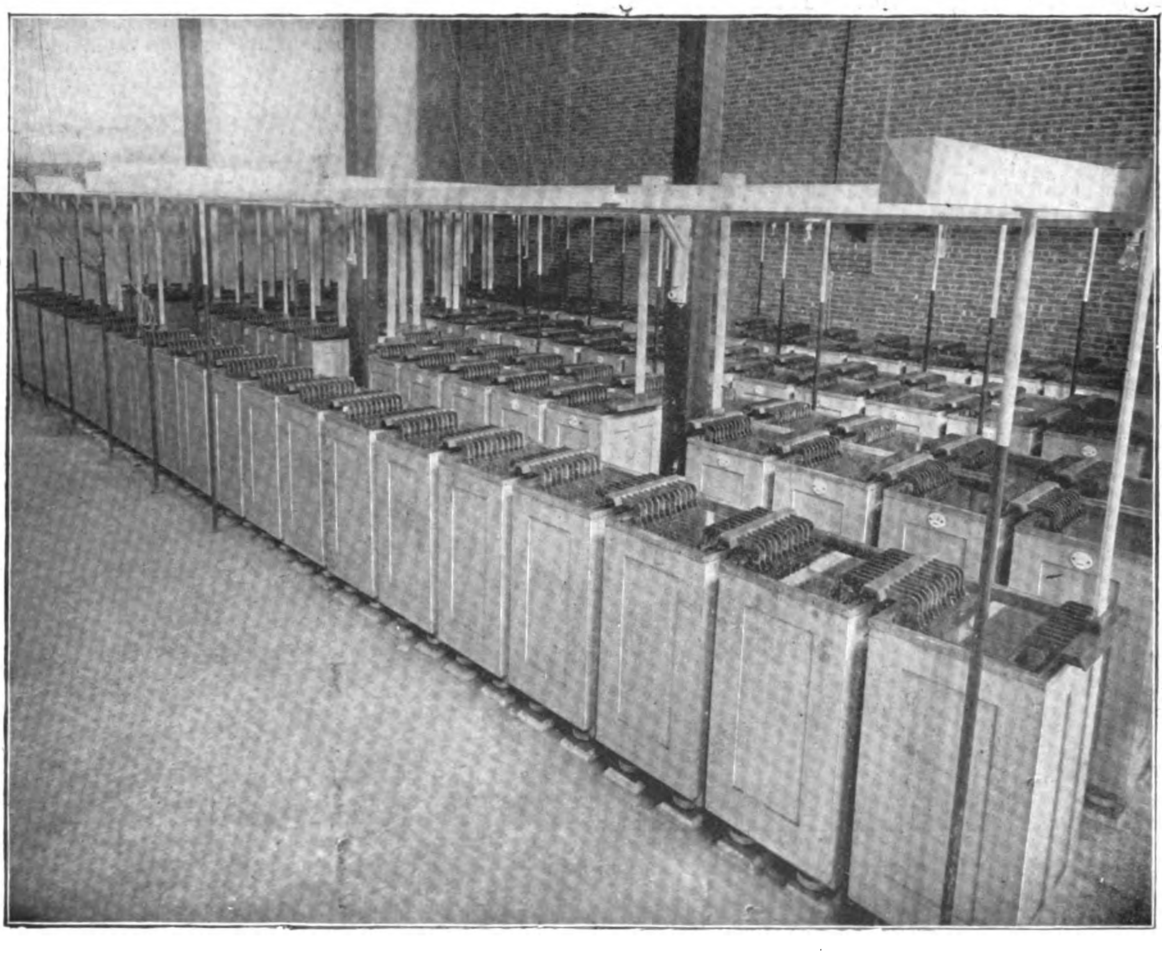

FIG. 44.—INTERIOR OF BATTERY SUB-STATION, BOSTON EDISON ELECTRIC ILLUMINATING CO.

The above mentioned stations are located as follows: The First, Second, and Third Stations are situated at three points which form approximately an equilateral triangle, the distance between Third and First being 3,800 feet, and between Third and Second 4,200 feet, the Fourth, or sub-station, being 7,000 feet from the First, or nearly 11,000 feet from the Third.

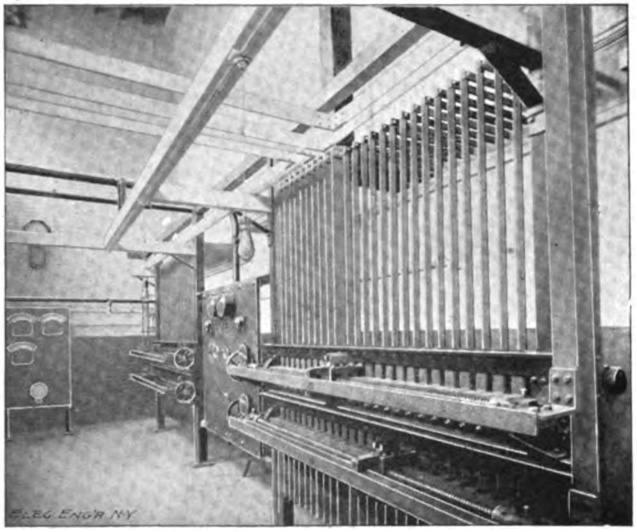

FIG. 45.—END CELL REGULATING SWITCHES, BATTERY SUB-STATION, BOSTON EDISON CO.

The First and Second stations are each connected with the Third by direct cables or tie lines of 3,000,000 circular mils capacity, on each side of the three-wire system, while between the First and Fourth it is so arranged that one of the feeders can be used as a tie line when desired.

This arrangement gives great flexibility to the system and enables the load to be divided up among the various generating centres in the most economical way.

Fig. 48 shows the total load on the system for a winter day, also the way in which it is distributed over the different stations. Curve A shows the total load on system. Curve B shows the load carried by the third district station. Curve C shows the load carried by the first district station. Curve D shows the load carried by the second district station, which at present has no storage battery, but where the new battery is being installed. Curve E shows the load carried by the fourth district or battery sub-station. The shaded portions show the load carried by the storage batteries, and the dotted portion the amount of charge given them at night.

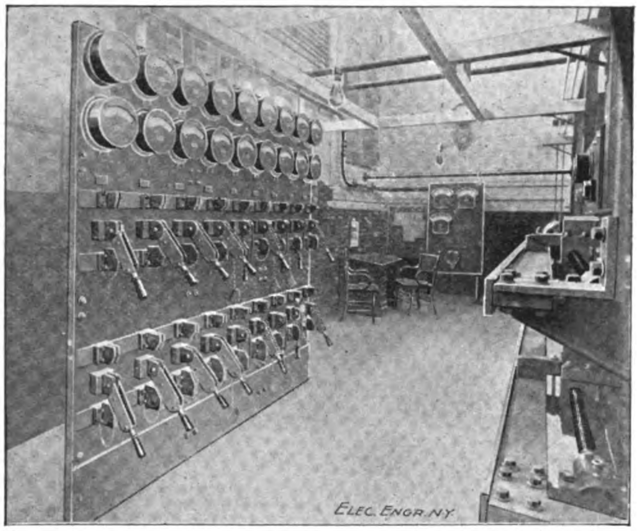

Fig. 46.—Main Switchboard, Battery, Sub-Station, Boston Edison Co.

This diagram does not illustrate fully the work done by the batteries, nor give an adequate idea of the important part they play in the system. For example: At the time of maximum load the batteries discharge at about 6,000 amperes while there is an available capacity in them of 13,000 amperes; this is due to the fact that while the third station battery is pretty well discharged during the peak, the first station battery is purposely not discharged, but is reserved in order to take the load in the event of the tie line giving out between the First and Third Station. It is used at a smaller rate of discharge on the residence lighting during the evening so that by midnight when the load is off the First station, the battery is about discharged. At the Fourth or sub-station, the load, being chiefly residence lighting, the maximum discharge does not occur till after the time of maximum load on the system.

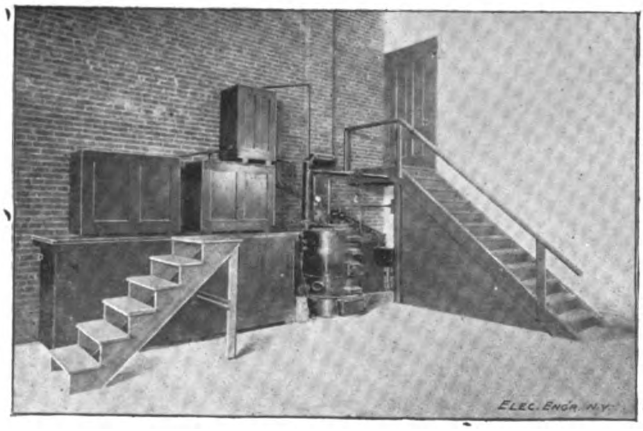

Fig. 47.—Water Still at Battery Sub-Station, Boston Edison Co.

By means of batteries arranged in this way, it is possible to generate the greater part of the output at the most economical station. For example: Ninety per cent. of the total output is generated at the Third station where the most efficient plant is installed.

The batteries are used continually during the day to equalize the load on the generators; when any units are becoming slightly overloaded the battery discharges in parallel with them and does away with the necessity of starting up a fresh unit, which would have to run at a light and uneconomical load. Again, if the load falls off so that any unit is not working at sufficient capacity to render it economical, it is used for charging the battery until the conditions are such that it can be taken off the system altogether or run at approximately full load.

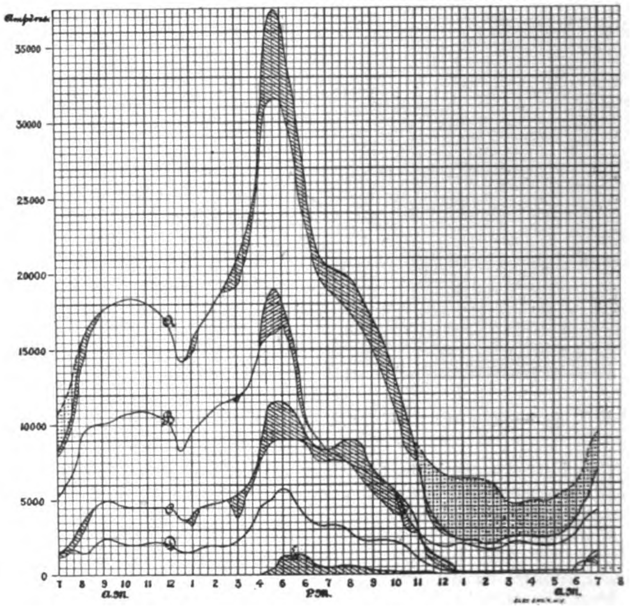

Fig. 48.—Curves Showing Load on Boston Edison Stations.

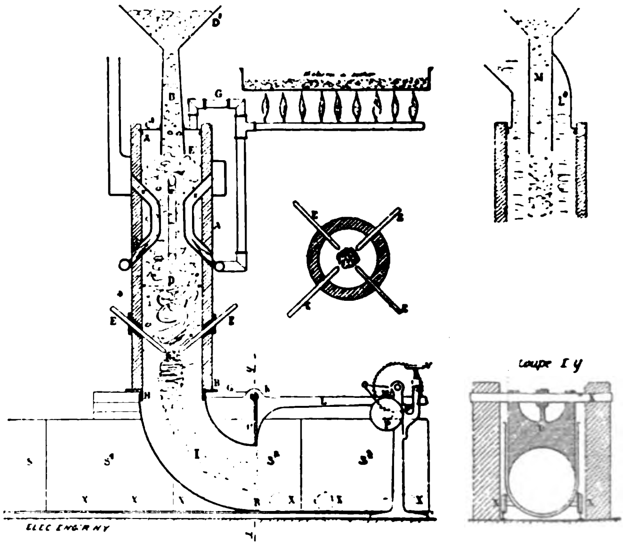
THE LELIEVRE ELECTRIC FURNACE.

THE great desideratum in an electric furnace is to obtain a continuous action, and also to obtain the best utilization of the heat produced by the arc. A furnace in which these these two conditions have been kept particularly in mind is that designed by Mr. E. Lelièvre, of Tours, France. As shown in the accompanying engraving, it consists of a cylinder A, of fire brick, or other resisting material, having a diameter D proportional to the output desired. About 50 centimeters above the base B are placed several electrodes E, either in even or uneven numbers and forming among themselves equal angles, the electrodes being either in the same plane or inclined towards each other. The multiple electrodes have the advantage of insuring perfect regularity of action by spreading the heat uniformly, and of allowing of their replacement without interrupting the action of the furnace.



The Lelievre Electric Furnace.

The bottom of the cylinder rests on a base plate G, having a cylindrical opening equal to that of the diameter of the furnace. Below the plate and corresponding to the opening there is a short cylinder H. The plate is carried by two parallel walls from which the elbow I descends at right angles, which elbow is carried on an axis centered at K, so that it can be moved absolutely concentric. The movement of the elbow is effected by the lever L, and the cam M by means of the gear and pinion at O. The number of oscillations are regulated once for all by the speed of the pulley, and the extent of the movement is regulated by the screw V, which limits the swing.

The end of the elbow R, is, so to say, embedded in a trough S, the lower part of which is a half cylinder, and the interior diameter of which is greater by several millimetres than the exterior of the elbow. The extremity of this elbow carries a casting U, forming with the opening of the elbow a surface similar to the transverse section of the trough. The sides of the latter are vertical and the trough consists of numerous sections, S, S^1, S^2, S^3, movable on a track.

The upper part of the furnace is closed by cover C^1. The middle of the cover has a hole through which passes a tube B^1, which is the charging tube, and extends below the cover about 25 centimeters. The upper end connects with a hopper D^1. The free space between the cover and the mass to be fused constitutes the gas chamber E^1.

The gas liberated is carried by a tube G^1 through to the condensing or liquefying apparatus, or to products with which they go to combine chemically. Since the escaping gases are generated in proportion to the amount of matter which goes into combination in the furnace, this gas when passed through a meter can thus be made to indicate the action of the furnace. Thus in the manufacture of carbide of calcium, for example, the carbonic oxide disengaged can be readily burnt, and the heat utilized to dry the carbon and the lime in the interior of the chamber, which is for that purpose traversed by the tubes K^1.

The top of the furnace may also carry a charging tube L^1, having a diameter equal to that of the furnace, and this same tube may carry at its center another tube M^1, reaching down 50 centimeters into the first. By this arrangement the material to be fused can be introduced into the center and the inert matter, such as carbon, placed in the tube. These two materials will then arrive without mixing into contact with the electrode, and the material to be fused will enter into fusion within the tube of the inert matter, which will thus always protect the sides of the furnace.

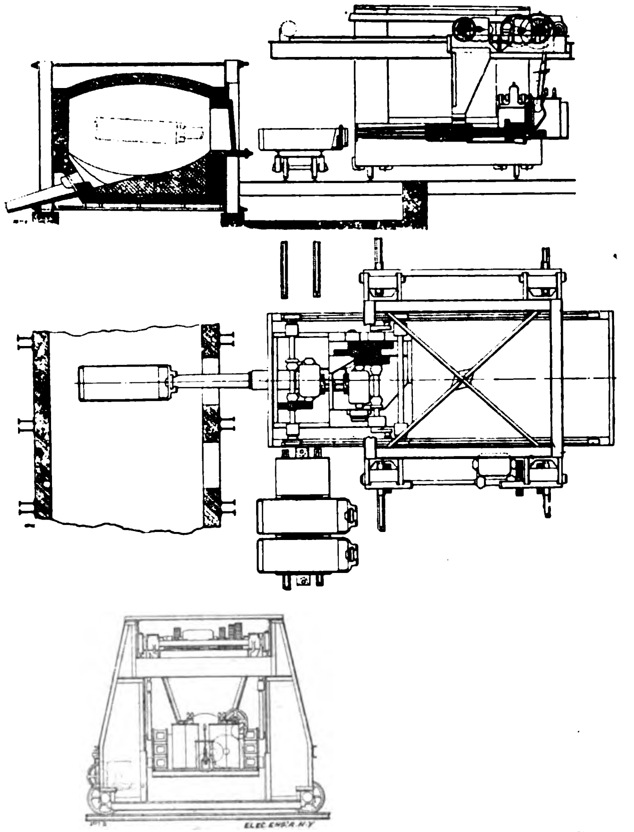
The action of the furnace is as follows: Before turning on the current the furnace is completely filled. At this period a part of the trough S is lined, and the elbow is full. The current is turned on and operation commences. Owing to the oscillating movement of the elbow the charge descends slowly, and is deposited automatically into the trough, which advances with every oscillation of the elbow. The full parts of the trough are emptied and replaced by others to be filled. The operation continuing, the material which enters into fusion, descends little by little in the elbow, traversing always the center of the material unfused and arrives finally in a pasty state, always surrounded by material, into the trough, from whence workmen extract it, after it is completely cooled. On the other hand, above the arc the gases produced by combustion have to take a long course through the midst of the charging material, and impart to it their heat.

WELLMAN ELECTRIC OPEN HEARTH CHARGING MACHINE.

In a paper read before the Institution of Mechanical Engineers, Mr. Jeremiah Head describes the Wellman electric open hearth charging machines which are employed at the Otis Steel Company's Works, at Cleveland, O. The machine illustrated represents the latest type of the Wellman machine, several of earlier types being still in operation at the works. Fig. 1 shows a cross-section of a furnace, the charging bogie with a charging box upon it, and the charging machine itself. Figs. 2 and 3 show the same in plan and back elevation. Downwards from the charger truck projects a strong bracket, ending in double-eye bearings, which carry a trunnion sleeve. Into this sleeve is threaded and secured with a back collar the charging bar. On the after end of the latter is carried the operator's platform, the tail end of which is connected by two rods with the pins of two cranks, keyed symmetrically to a shaft running across the charger truck frame at its rear end.

A motor carried on the truck is connected by gear with this shaft. By switching on the current the operator can rotate the crankshaft in either direction, and so move the charging bar up or down like a heavy gun in its trunnion bearings. As the motion is of the "all-round" type, no harm can come from overrunning. On the charger truck is also mounted a motor and gear for moving it and the charging bar, and all connected therewith towards or from the furnace by operating on the front axle and wheels.

The motors for producing the requisite movements are each 25 horse power, except that on the operator's platform for twisting the charging bar, which is only 3½ horse power. But as the maximum effort is seldom required in any of the movements, and as they are successive and not concurrent, 25 horse power may be considered the maximum used by them all at any one time. The power continuously used does not in all probability exceed an average of 10 horse power whilst the machine is at work. The current, which is brought by a single pair of conductors running overhead along the charging platform, is conveyed to the operator's platform by sliding contacts, to be there distributed to the various motors. The new high-framed machine has a great advantage over the old low-framed ones, in that it admits of the necessarily bare conductors and contacts being kept high up and well out of the way of the traffic in the floor. The power at the central station may and should be generated by economical engines under favorable conditions. Little pressure is lost in transit, and no current is taken by the machine except when at work, and then only in proportion to the work actually done. The motors are of a simple type, encased in iron, like those so common in America for use under electric street cars. The current is a continuous one, and the voltage used is 220 to 250.



Figs. 1, 2 and 3.—The Wellman Electric Open-Hearth Charging Machine.

The charging boxes are 6 feet long by 2 feet broad and 1¾ feet deep, which gives a capacity of 21 cubic feet. This is sufficient to contain a ton of ore or scrap and more than a ton of pig iron. Except when heavy castings and cobbles are to be dealt with, a ton is a convenient average load for a charging box, and 3 or 4 tons for a charging bogie, according to whether it is made to carry three or four boxes. If the boxes are properly loaded, the machine will pick up and empty one every minute, which is equivalent to dealing with an entire charge of 48 tons in 48 minutes. Allowing 12 minutes for contingencies, a charge would occupy one hour instead of 3½ hours, which is an ordinary time required for charging a 40-ton furnace, exclusive, say, of one hour for fettling. This would be required in either case. Thus a saving of 2½ hours per charge is effected by the machine. The time gained per week by using machine against hand labor may be expected to be at least 2½ hours x 9 heats = 22½ hours, which is more than sufficient for an extra heat or an increase in the total output of one-ninth, or 11 per cent.

Charging machines are also in operation in the Homestead Works, of the Carnegie Company; Illinois Steel Works, South Chicago, and the Cambria Iron Works, Johnstown, Pa.

THE DIRECT CURRENT TRANSFORMER.[1]

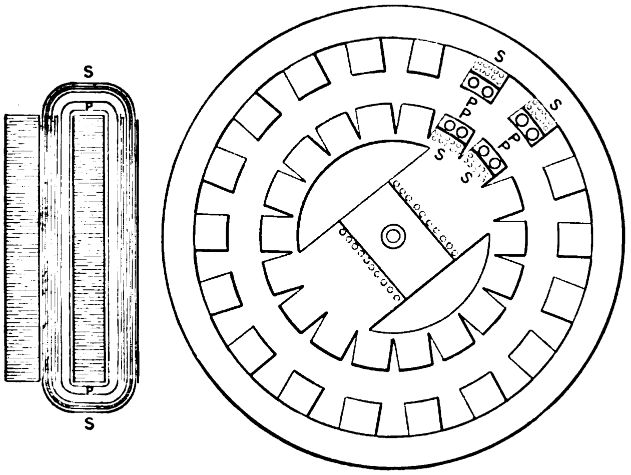
By C. THORDARSON.

THE direct continuous current is the ideal method for transmitting electrical energy, and it has advantages over the alternating current in almost all cases, and embraces a broader field, as for instance, the operation of the telephone and telegraph systems which cannot at present be operated in any other way.

The objections to the direct current transformer are not so much questions of efficiency (for this can be made as high as the alternating) as it is the first cost and running expenses. Now the first cost of the machine is a factor that cannot be greatly diminished. An apparatus having bearings, commutator and brushes will necessarily cost more than one having only two coils encased in a stationary magnetic field.

As regards the running expenses which constitute the wear and attendance, a direct current transformer of over 75-kilowatt capacity can be designed so as to require very little attendance, and experience has shown that an alternating transformer of the same output does require some attendance. Here therefore the difference between the two is not very great. When we come to the transformation in very small units the running expense of the direct current transformer has frequently been so high that it could not compete with the alternating current.

Let us first consider the friction on the bearings which if the armature is well balanced, is chiefly from its weight and sometimes from lateral pressure. The lateral pressure on the bearing can be entirely prevented by having the armature core of the same width as the field magnet poles, and the free space between the bearings and commutator the same as the length of the air space from armature core to field cores. But these proportions are only approximately true, and will vary some with slotted and surface wound armatures. When so designed the magnetic field will hold the armature absolutely free from all lateral thrust under all variation of load.



Elec. Eng'r. N.Y.

FIG. 1.—THE THORDARSON CONTINUOUS CURRENT TRANSFORMER.

The bearing friction caused from armature and commutator weight can be greatly diminished by mounting the armature eccentric or above the center in its running space. In this way the pull of the magnetic field will in smaller machines almost entirely counterbalance the weight of the armature and commutator. These are peculiar advantages of the rotary transformer, which when properly applied in the design can be produced in any dynamo and motor of the same output, there being no pressure on bearings from ropes or belting as the power is only transmitted between coils that are mounted on the same armature core.

To diminish bearing friction caused by armature weight it is profitable to use the bi-polar type on small units and to avoid friction from lateral thrust; all types having the field poles by the side of the armature as the Brush machines are objectionable.

Over a year ago I designed a 200-watt direct current transformer embodying most of these principles. It has run as long as 90 hours continuously without any attendance whatever.

In working out various designs of direct transformers the idea of rotating brushes and keeping all the other parts stationary will naturally suggest itself. Considerable experimenting has been done in this direction, especially by the Westinghouse and General Electric Companies, but very little of this information has found its way into print. A year and a half ago I designed and constructed a machine on this plan, Fig. 1, taking an ordinary laminated ring slotted on the external edge, and into each slot was wound one primary and one secondary coil, and over this ring was slid another laminated ring of the same width and sectional area, thereby encasing each pair of coils in a closed magnetic field; the leads were connected to a stationary commutator. Inside of the ring was mounted on a vertical shaft a field magnet of sufficient strength to produce rotation, and on this shaft were secured the arms carrying brushes and collector rings. The results might have been predicted. Each pair of coils acted as if it were an independent static transformer.

This is like taking so many static transformers, placing them anywhere at random on the floor and connecting them to commutators; they will give the same results. We have in both cases induction and an immense amount of sparking, and the sparking is so violent that it is difficult to run the apparatus even through an experiment. The advantages of slotted armatures are well known and spreading of the core teeth greatly diminishes the magnetic reluctance of the air space. If the coils are deeply sunk in the core and the slots closed over them the self-induction caused by the closed magnetic field surrounding each coil will become troublesome.

Even if there were no sparking this type of machine would be immensely more complicated than one having armature and commutator rotating.

Direct current transformers are at present chiefly used for operating telegraph and telephone circuits. For telegraph circuits the machines are required to give varying e. m. f. For that reason the primary and secondary circuits must be in two independent magnet fields, for no satisfactory variation of e. m. f. on the secondary can be made in any other way. The simple direct current transformer having primary and secondary circuits in the same magnetic field will vary its speed to maintain constant e. m. f. on the secondary.

THE DIRECT CONVERSION OF HEAT INTO ELECTRICITY.[1]

BY HARRY BARRINGER COX.

THE lecturer introduced his subject by stating that he was led to take up the study of thermo-electric generation by seeing an article in a newspaper to the effect that there were three great inventions to come: (1) The direct conversion of heat into electricity; (2) light without heat, and (3) a successful flying machine. He concluded that the greatest of these problems was the direct conversion of heat into electricity, and immediately took up the work with the courage and confidence of youth, little dreaming of the years of hard work before him.

Mr. Cox then described his first crude attempts at constructing a thermopile, which were unsuccessful. After many experiments Mr. Cox came to the conclusion that the success of an apparatus of this kind did not depend solely on its efficiency, but also on its cost and durability, cost of attendance, etc. As a result Mr. Cox paid very little attention to thermo-electric couples from the standpoint of their electromotive force. His chief attention was paid to this: that thermo-electric couples were deficient, not so much in their electromotive force, but in their mechanical construction. When he came to undertake the removal of the drawbacks to the thermo-generators of the past Mr. Cox was quite alarmed to find so many difficulties in one problem, conceding it to be a simple problem. He found, first, if one joined two metals together, that there was a great liability to oxidation of the joint. The oxidation would, of course, affect the output of the machine by cutting down the current to practically nothing in the course of time. Then there was the serious difficulty of the disintegration of the element, its breaking apart or disruption: thus one might have an element which would be all right and apparently strong to-day, but would, owing to defective structure, rupture or break apart without warning. No practical machine could be made with any such couple as that. Conceding that both these difficulties could be corrected there was still another very serious difficulty in the couple, and that was the fact that they were so fragile that, taking a couple of three-quarters of an inch in thickness, one could take it in one's fingers and crush it almost to powder; it was totally impracticable from a commercial standpoint. Mr. Cox then explained that his couples are made of two parts antimony and one of zinc, which is Seebeck's old metal, which he used back in 1821. The cross-connection piece is made of copper. These couples are now made by machinery. There is no soldering or brazing or joining, except a machine joint. The castings are made in a special room, the room being heated up to a considerable temperature. All the work is done under as high a heat as it is possible for the men to stand. The parts are dropped into the machine mold, and the couples are made quicker than it would be possible to count; fifteen are cast at one time. They will in a very short time, be running a machine which will make a casting which goes from the bottom clear to its top, with absolutely no joint in the entire device.

---

[1] A paper read before the Chicago Electrical Association, May 7, 1897. Abstract.

[1] Abstract of a lecture delivered before the New York Electrical Society, May 20, 1897. With discussion.

In making this casting, it is not a joining of the cross strip with the lug, but it is a shading of one into the other. There is really no line of demarkation, no line where there is a joint; as there is no line of demarkation, it is impossible even to imagine where there might be a rupture or oxidation.

In thermo-electric couples it has been stated that the closer we could get to the surface, where the heat is applied, the higher the electromotive force. Mr. Cox does not find this so. Instead of putting the junction at the surface, he lets it in a distance, which very materially tends towards lowering the internal resistance of the lug; he finds no decrease in the electrical output from the standpoint of e. m. f.

After the thermo-electric castings are made they are subjected to a Wheatstone bridge test to get the internal resistance when cold. Strange to say, these thermo-electric couples as built give a current at all times absolutely independent of the fact whether heat is applied or not; there is a difference of potential indicated at all times. By approaching the hand to one side or the other, the needle of the testing galvanometer is brought to zero, the heat of the hand being sufficient to establish equilibrium. After the castings are made and tested they are formed upon a spindle and the connection of the castings brazed together. Using five castings, with a total of seventy-five junctions, made in five different operations, requires only ten minutes. The completed couples are then labeled as having an internal resistance of so much. After they are built up, the interior is cemented with vitrified cement. When it is all cemented, the plates which have held the built-up device are retained, and it is put in an oven and baked and vitrified. It is then tested again; and all this time it has the tag on it which it started with, which indicates the internal resistance when first built up, and the internal resistance during the various processes of its manufacture. The outside of the machine is then cemented and baked as well as the top and bottom. If it passes the bridge measurement its jacket of metal is cemented on and firmly joined to it, becoming an integral part of the cement and of the machine itself.

This cylinder so formed is then encased in a water-jacket and tested under 15 pounds water pressure for leakage. After the water pressure test has been completed, the machine is submitted to heat, slowly applied, in order to thoroughly vitrify the inside, and then a final resistance test is made of the machine, which must correspond with the original test. Each generator is tested for one week. Taking the machine, as it was running on the table before him, Mr. Cox said there was about 2½ cubic feet of gas used in the machine for the work which it was then doing (running a small fan), that costs at the ordinary rate of New York gas, which is extremely high, three-tenths of a cent to operate the fan motor per hour. In the heating of the generator a deflector is employed which gradually increases in size. The hottest part of the flame being at the bottom, it is the smallest in the deflector bar, and is furthest away from the sides of the device, and the higher up the flame goes the larger it gets, and the greater the heat is confined. The device works very efficiently. Mr. Cox explained that there was no danger of the deflector bar of iron wearing out by being run constantly at red heat, as the carbon burned out of the iron is redeposited on it from the Bunsen flame, the action being similar to that of the Bower-Barff process for making iron non-rusting. Mr. Cox then showed that the generator could operate a six-inch gong, a medical coil, a telegraph instrument and a fan, which were on the lecture table, all at one time.

As to the future Mr. Cox believed that we had reached the limit of thermo-electric efficiency; the question was now purely a mechanical one. He had constructed machines built exactly on the lines of the one shown, only larger, which ran five 16-candle-power lamps of full photometric value, for one cent per hour. His ultimate idea was to produce an efficient mechanical working device with a very high amperage output and low voltage. He did not attempt to attain extremely high voltage. He did not believe it would pay.

The water in the machine, according to Mr. Cox, has very little to do with its working. He does not find that the cooler the backs and the hotter the fronts, the greater the output. He had never found any such condition as the one just stated, that the hotter you make the hot junction, and the cooler you make the cool junction, the greater the electrical efficiency. He found that if one gets the cool junction too cool the efficiency of the hot junction is reduced, and one must be careful not to get the device too cool. A temperature on the outside between 60 and 185, only reduces the electromotive force a few tenths of a volt in a five-volt machine, and that is not due to the thermo-electric effect, but to the increased internal resistance which of necessity the excess of heat produces. He had tried it with freezing water, and confirmed his statement.

In reply to questions by various members Mr. Cox stated that the machines were built for 2.5, 4.5 and 10 volts. The 4.5 volt machine gave 4 amperes, and it contained 75 couples, in 5 rows of 15 each. On the higher voltage machines, the current output is less proportionally than with the low voltage machines. The generators could not be run economically above a certain temperature owing to the increase in internal resistance.

MR. G. S. DUNN suggested that a very simple way to measure the output would be to short-circuit the machine through the ammeter. Then we know when it is giving half the number of amperes it is giving the maximum number of watts at half the voltage on open circuit.

PROF. F. B. CROCKER: I think Mr. Cox is right in saying that there was no necessary disintegration in the thermo-electric pile. I have heard the statement made on high authority that there was an inherent deterioration; in fact, that the pile acted by that very deterioration; in other words, that its life was limited by its activity, and the more work it did the shorter its life. I do not think this is either theoretically or practically necessary. I do think, however, as Mr. Cox has said, that it requires a very perfect and perhaps peculiar mechanical construction to avoid the natural disintegration which is likely to occur when we join dissimilar metals. That sharp line of demarkation, to which he refers, as is well known, tends to produce a weak point and the elements are very likely to crack at that line of demarkation; but by some particular construction, one or two of which he has indicated (and there are several others), we can avoid that, not only partially, but entirely. I am familiar with thermo-electric couples in use a year without any serious depreciation in value of their output; and in fact we have a battery in our museum in Columbia College which we have had for several years, not used constantly, but more or less, and as far as I know it is as good to-day as it was several years ago. That difficulty I think can be, and practically is, overcome. In regard to the oxidation, I think that can be overcome by protecting the elements in some such way as Mr. Cox speaks of. In the case of the elements I speak of, each element is protected by a shoe, on which the heat strikes and that protects the elements from oxidation.

As to the output, as Mr. Dunn has said, the amperes on short circuit give twice the amperes registered when the external resistance equals the internal. At the same time we get only half the volts in the external circuit that we get on open circuit; and therefore if we multiply one-half the amperes given on short circuit by one-half the volts on open circuit, we get the actual watt output, which is the maximum to be obtained from any source of that kind, thermo-electric or otherwise. I have tested some electric batteries repeatedly, and that has come out correctly. You also get half the voltage when you have the external equal the internal; half the total voltage is available from the external circuit. It is a well-known fact, and is, of course, true in this case.

Concerning the hot and cold juncture or junction, differing in temperature, I have observed the same fact as stated by Mr. Cox that if you cool or reduce the temperature of the cool junction, and make it still cooler, you do not get a much increased electromotive force. Mr. Cox interpreted that to mean that a greater difference of temperature does not give a greater electromotive force. In that conclusion, from that observed fact, I do not agree, because I think it is a fundamental law that the electromotive force is proportional to the difference of temperature. It is used in physics as an absolute method for the determination of temperature and when it is used at low temperatures it is even more reliable than a thermometer. The law is that the electromotive force is in proportion to the difference of temperature. It is true of this battery as in every combination of thermo-electrics. I explain that phenomenon, which is undoubtedly observed, in this way: If you cool the junction having the lower temperature, the other one follows it down, and you simply have practically the same difference of temperature as before. You say why? Does not the higher temperature remain at that higher temperature? No; simply because it has a limited heating surface and can only maintain a certain difference of temperature between the ends, and if one end is cooler, the other will only be the same number of degrees above it in temperature, and if the cool one goes down, the higher temperature then follows and maintains the same difference between the two ends, or substantially so. (Applause.)

It always struck me that it does not pay to cool by water or otherwise the cool junction. I tried it and found if we drop cold water on the cool junction, or even put ice on it, there was no great increase in the electromotive force. Therefore, I argued it was not worth while to complicate the device by attempting to cool the lower temperature junction. It has been suggested by Mr. Bradley, who is present, that the thermo-electric battery is just like a boiler; that it has a capacity of output proportioned to its heating surface. In a boiler we have so many square feet of heating surface and there is so much possibility of producing energy. If more attention was paid to the fact, we might increase the heating surface of the battery, and get a greater difference in temperature, which I feel positive will give a greater electromotive force.

In regard to the small number of couples, Mr. Cox is right in preferring a smaller number, and therefore less complication, provided he does not need a higher electromotive force. If it is necessary to have a higher electromotive force, he suggests that it can be obtained by transformation. Unfortunately, the only way of transforming direct current now open to us, is by means of the motor dynamo, a fairly good device, but having an efficiency of not much more than 85 per cent., and that is somewhat of a disadvantage. Perhaps it would be better to have a fewer number of larger couples, and sacrifice efficiency in order to get simplicity with a few couples. If I wanted a hundred volts I would rather get it by a sufficient number of couples than by a small number of couples and a motor-dynamo.

MR. JONES: What is the difference in the internal resistance with 75 degrees? Is it possible to put several of the machines in series like a battery, and will they act in the same way as the cells of a battery?

In reply to Mr. F. W. Jones, Mr. Cox said that the generator could be treated exactly as though they were primary batteries; they could be put in series or multiple to any extent. Regarding the difference in resistance between the machine hot and cold, he finds it to be about three-tenths of an ohm to one ohm; if it has an internal resistance of one ohm cold it is about 1.3 ohm hot, representing a difference of 75 degs. in temperature. The generators could be short circuited.

MR. DUNN, at the request of the president and Mr. Cox, tested the machine to get the watt output. He first connected the volt-meter across the terminals on the left-hand pole on open circuit, which showed a voltage of 2.6. He short-circuited to the ammeter, and got a current of 3.9 amperes. Taking half of each of these values and multiplying them, he got an output of 2.53 watts.

MR. COX: This machine which Mr. Dunn says is only giving 2.53 watts is running that fan motor. (Applause.)

D. M. I. PUPIN: I would like to say a word in support of Mr. Cox's views. I do not think the test which Mr. Dunn made is quite unobjectionable. I think where a battery can work with the expenditure equal to the supply, the theory is right about the watts; but suppose the battery gives current at a much larger rate, and does its work at a much larger rate, than the supply of energy; then, of course, the voltage would drop. A battery is not the same thing, when it gives this large current, as it is when it gives the small current. It is quite possible, if a thermo-electric battery is short-circuited, and gives a large current, that the gas jet is not capable of supplying the heat at the rate at which the electrical energy demands it, and the actual voltage of the thing drops, and then the battery would not work under the same conditions as it would work if the heat supply was large enough to keep the actual induced difference of potential constant. It is a fact similar to the polarization cell; and when I see this motor work at 2.5 watts, as stated, I do not believe that it can do it.

MR. C. O. MAILLOUX: I do not think the Peltier effects should be neglected. As there is a self-induction in dynamos, so there is a counter phenomenon in thermo-electric currents, whereby the passage of the current changes the temperature. When the current is increased beyond the normal rate for which the instrument is designed, there would be a strong phenomenon which would act in a manner analogous to the self-induction and act as a counter electromotive force. I think it is an effect which should not be neglected, and which would make the actual current smaller than might be thought.

A PRESIDENTIAL CAR is what the Railroad Car Journal proposes to have built by public liberality for the personal and official use of the successive Presidents of the United States. There is an advisory committee of 25 expert car builders and superintendents of motive power, and offers of material, appliances, etc., should be sent to them at 132 Nassau street, New York City.

TELEPHONY AND TELEGRAPHY

CONVENTION OF INDEPENDENT TELEPHONE COMPANIES AT CHICAGO.

A CONVENTION of the Independent Telephone Companies of the United States was held in Chicago on Thursday, May 27 and two following days. The first session commenced at 10 o'clock on the morning of the 27th at 250 South Clinton street. The principal matter of importance which came up at this meeting was the election of a committee of ten and a chairman to appoint an executive committee of two from each State.

At the afternoon session, which took place in parlor N, Palmer House, after Mr. J. E. Keelyn, who was elected chairman of the convention, called the meeting to order, the Committee of Ten proceeded to appoint the executive committee of two from each State to formulate and devise plans for the purpose of organizing a national association in the interests of the independent telephone companies and to draw up a constitution and by-laws of the association.

The following executive committees were appointed: Chairman, T. A. Marshall, Keithsburg, Ill.; secretary, J. H. Vesey, Cairo, Ill.; J. E. Keelyn, Chicago, Ill.; W. H. Gilbert, East Saginaw, Mich.; D. McVichey, Ishpeming, Mich.; J. Slade, Oscaloosa, Ia.; Judge Stevens, Boone, Ia.; W. L. Miller, La Crosse, Wis.; W. A. Harper, Madison, Wis.; H. E. Ralston, Maryville, Mo.; E. C. Baker, Cameron, Mo.; W. B. Seaton, Ashland, Ky.; H. C. Cole, Owensboro, Ky.; H. E. Matthews, Huntington, West Va.; J. M. Payne, Charleston, West Va.; W. P. Roberts, Lynchburg, Va.; S. A. Duvall, Richmond, Va.; Clarence Hodson, Baltimore, Md.; C. E. Frink, Westminster, Md.; W. H. Rankin, Elizabeth, N. J.; H. C. Dow, Cobleskill, N. Y.; W. H. Laird, Wyona, Minn.; L. C. Ketcham, Palestine, Tex.; L. C. Baker, Beaumont, Tex.; R. B. Lebby, Charleston, S. C.; J. H. Twitchell, Spartansburg, S. C.; I. Newton Smith, Tarboro, N. C.; J. Brown, Montpelier, Vt.; G. H. Almond, Montpelier, Vt.; J. A. Evans, Rome, N. Y.; J. Stewart, Natchez, Miss.; J. Crane, Yazoo, Miss.; Hon. J. N. Thomas, Chillicothe, O.; J. H. Critchfield, Mount Vernon, O.; H. C. Young, Columbia, Pa.; C. R. Savidge, Sunbury, Pa.; Dr. J. A. Lumbkin, Mattoon, Ill.; J. L. Stone, Rushville, Ind.; G. W. Beer, Fort Wayne, Ind.; J. Burke, Carbondale, Ill.; C. Truitt, Columbia, Mo.; J. Leak, Cairo, Ill. At the termination of the first day's proceedings the meeting adjourned until 9 A. M. Friday morning at the Palmer House.

The telephone men opposed to the Bell interests, met again in session at the Palmer House, on Friday and adjourned, after deciding on a national convention in Detroit on June 22. The coming convention's purpose is to unite the anti-Bell exchanges, and the gathering was recommended by the executive committee. Manufacturers and dealers in telephone supplies were requested to meet also at the same time and place.

J. E. Keelyn, president of the Western Telephone Construction Company, who had been chairman at the Palmer House session, asked to be relieved, and J. L. Thomas of Chillicothe, O., was chosen therefore to preside. W. J. Veasey of Fort Wayne was made secretary.

A resolution commending Justice Harlan of the United States Supreme Court for his dissenting opinion on the Berliner litigation was introduced by L. Z. Holbrook of Chicago, but withdrawn, delegates saying it would be unwise to express an opinion of the action of any of the Supreme Court judges, in view of future litigation.

The executive committee, representing various States of the Union, met after the convention adjourned and appointed the following sub-committees:

By-Laws—C. R. Savidge, Sunbury, Pa.; H. D. Critchfield, Vernon; O.; Dr. I. A. Lumbkin, Mattoon, Ill.

Resolutions—J. L. Stone, Richmond, Ind.; Hugh Dougherty, Indianapolis, Ind.; A. T. Averill, Cedar Rapids, Ia.

Thomas A. Marshall of Keithsburg, Ill., chairman of the executive committee, was appointed to consult the railroads as to rates for the Detroit convention.

THE POSTAL TELEGRAPH COMPANY reports that this summer it will have an office in every city and town of importance in Texas. A great deal of extension work has also been done in New York State.

INDEPENDENT TELEPHONE MEETINGS IN INDIANA AND PENNSYLVANIA.

A special dispatch from Pittsburg says: The first annual meeting of the Interstate Local Telephone Association will be held at the Monongahela House June 3. Fifty-five distinct, independent telephone companies in western Pennsylvania, eastern Ohio and West Virginia are expected to have representatives at the meeting. Invitations have also been sent to the telephone companies at Sunbury, Shamokin and Mount Carmel to send representatives to the meeting. The people interested in the meeting expect to discuss the recent United States Supreme Court decision in regard to the Bell patent. They are prepared to defend themselves in any legal emergency and are negotiating for the services of a well known telephone lawyer to become their counsel. There are prospects of an immense combination of small telephone concerns of the United States this summer in opposition to the Bell company. A convention of companies will be called for some central point within the next few months, when the possibilities of extending the long distance system will be considered. The independent companies in this State do 75 per cent. as much business as the Bell company, it is understood, and in the small towns, where they have their principal business, have much more. In Greensburg they do about three times as much; in New Castle about five times as much, and in Carnegie they have nearly all the service. Independent telephone companies of this city and vicinity are having nothing to do with the convention in Chicago this week.

A dispatch from Fort Wayne, Ind., says: Representatives of the independent telephone companies from Ohio, Pennsylvania, Tennessee, Virginia, Michigan, Missouri, Illinois, Indiana, Arkansas, Iowa, Minnesota, South Carolina, Wisconsin and Texas are holding a meeting here to devise a means to formulate a toll system in opposition to the Bell Telephone Company. This meeting was addressed by Judge Robert S. Taylor, on the Berliner patent situation. It will be remembered that Judge Taylor took part in the prosecution of the Government suit against the American Bell Telephone Company.

ALLEGED WHOLESALE TELEPHONE SUITS AGAINST SUBSCRIBERS.

Reports have been current as to the intention of the American Bell Telephone Company to bring suits on a larger scale that has ever before been known in the annals of litigation. Such stories lack confirmation, but a high official in the local Bell Telephone Company at Pittsburg is quoted by the newspapers there as follows: "Our company has been a heavy loser by the competition of these concerns infringing on patents for which we have been paying a royalty. We expect to get some return for our loss. While I am not familiar with the course the American Bell Telephone Company will pursue, still I have heard it intimated by the officials that something is going to drop, and drop hard.

"Suits will be entered against everyone infringing on the patents, if I understand it, although time enough has not elapsed since the Supreme Court decision was rendered in our favor to prepare any plan of action. It has been intimated to me that the American Bell Telephone Company will change its plan of action. Heretofore it has been the policy of the company to enter suits only against the concerns making the telephones and those disposing of them for service. I have heard that a different policy will be adopted, and the individual user of the telephone will be made to answer for the infringement on the patent as well as those profiting by the transaction.

"I believe this is good law. If the subscribers did not subscribe for the apparatus that is duly patented and sustained by the courts, the concerns entering the business could not exist, and that would settle all opposition. The subscriber is directly responsible for aiding and abetting the infringement and should be held equally responsible."

INDEPENDENT TELEPHONE MOVEMENT IN BOSTON.

Five hundred circulars were sent out on May 25 from Boston to as many independent exchanges and manufacturers, calling for a meeting to be held at an early date in Boston, to form a combination to fight the Bell Telephone Company. As soon as a sufficient number of replies have been received a meeting will be called and some form of organization adopted. In the opinion of the projectors, the effect of this combination will be far-reaching and means that the independent companies have determined to band themselves together, pool their interests, and have the matter settled once for all. The call is the result of numerous requests by many independent exchanges in the East, and was sent out by Whitman & Couch, of Boston. The circular states that the call is made for a meeting to decide what means can be taken for mutual protection against the Bell company in case of suit, and also some means of consolidation whereby all the exchanges in the East may have a bond of fellowship and good will, and, in the near future, extend their lines for long-distance work and connect with the Western exchanges.

Mr. Whitman, of Whitman & Couch, said that the meeting to be held in Boston would work in harmony with the Western movement. It is practically a branch meeting for those who cannot afford the time and money for a trip to Chicago. The combination will be among the independent exchanges and the larger manufacturers who build and have an interest in these exchanges. With a firm combination the independent exchanges will have no fear of the Bell company in the courts, in fact, they will welcome a legal fight; and, if the Bell company does not take the initiative in the matter, the new combination will force it and fight the matter to the end. It is proposed that each organization in the combination shall contribute a proportionate sum of money in cash to the general fund, which shall be deposited in the hands of a board of trustees or directors. The great fight will come over the Berliner patent, and those interested in the movement believe that they could not lose if the matter were fought to the end.

ASSESSING TELEPHONE PROPERTY IN KANSAS.

An agitation has been aroused by the sudden multiplication of the assessment on the property of the Missouri and Kansas Telephone Company, at Topeka, Kan. The company has its headquarters in Kansas City, but the president, John R. Mulvane, lives at Topeka, and says he will fight the case to the Supreme Court. Heretofore the company has been turning in its statement of property at $4,000. This year there was a new assessor and the company raised its statement of property to $5,000. This did not suit the assessor, and he made it $35,000. He claims the plant cost over $100,000.

BELL TELEPHONE OUTPUT.

The American Bell Telephone Company's statement of instrument output for the month ended May 20 and the year to date shows:

May—	1897.	1896.		
Gross output	20,598	20,001	Inc.	597
Returned	452	7,537	Inc.	915
Net output	12,146	12,464	Dec.	318
Dec. 21 to May 20—				
Gross output	94,333	96,519	Dec.	2,186
Returned	36,608	35,999	Inc.	609
Net output	57,725	60,520	Dec.	2,795
Total telephones in hands of licensees of the American Bell Company under rental				830,014
Against total one year ago				735,496
Comparative increase				94,518

LEGAL NOTES

VAN DEPOELE PATENTS ON TROLLEY SWITCHES AND TRAVELING CONTACTS SUSTAINED ON APPEAL.

Appeals from the Circuit Court of the United States for the Northern District of Ohio. Submitted Feb. 27, 1897. Decided May 17, 1897.—Before Taft and Lurton, Circuit Judges, and Clark, District Judge.

THESE were appeals in two patent cases between the same parties that present questions of such a similar character that they were argued together and were disposed of in one opinion. The appeals were from orders of preliminary injunction made before a hearing upon the merits. The first case was a suit by the Thomson-Houston Electric Company to enjoin the alleged infringement by the Ohio Brass Company of U. S. Patent No. 424,695 for suspended switches for electric railways, issued to Charles J. Van Depoele, April 1, 1890, and assigned by mesne assignment to the complainant. A preliminary injunction was issued against the making and selling by the defendant of overhead conductor switches for electric railways for use in the combinations covered by the 3d, 4th and 11th claims of the patent. The second case was a suit by the same complainant against the same defendant for an alleged infringement of U. S. Patent No. 495,443, issued to Charles J. Van Depoele for suspended switches and traveling contacts for electric railways and assigned by mesne assignments to the complainant. A preliminary injunction before the hearing on the merits was granted, enjoining the defendant from the manufacture or sale of trolleys or trolley bases intended to be used in the 6th, 7th, 8th, 12th or 16th claims of said patent.

It appeared in the first case that in a suit before Judge Coxe in the Northern District of New York, the validity of patent No. 424,695 was in issue and the validity of the claims involved were sustained. (69 Fed. Rep., 357). The cause was carried to the Circuit Court of Appeals for the second circuit and the order of injunction so far as the claims here involved were concerned was affirmed, though the complainant was required to enter a disclaimer as to certain other claims in the patent, to-wit: The 2d, 9th and 10th, which disclaimer was duly made and filed in the Patent Office. (71 Fed. Rep., 396.)

In the second case it appeared that the validity of patent No. 495,443 had been at an issue in a cause heard upon its merits and passed to final decree before Judge Townsend in the District of Connecticut and that the claims of the patent here involved were sustained.

There were two principal objections made in this court to the injunctions below. The first was that there was not any proof of actual infringement or of an intention to infringe the combinations covered by the claims set forth in the orders of injunction appealed from. The second objection was that the patents, Nos. 424,695 and 495,443 were both void, the latter because the former a patent of earlier issue, was for the same invention; and the former, because patent No. 397,451, a still earlier patent, issued to the same patentee, covered and was also for the same invention.

The Court of Appeals delivered a voluminous decision overruling both objections and sustaining the preliminary injunction.

TROLLEYS ENTITLED TO MORE PRIVILEGES THAN OTHER VEHICLES.—A PENNSYLVANIA DECISION.

IN deciding in favor of the Electric Traction Company, of Philadelphia, an action for personal injuries sustained by a child, the Pennsylvania Supreme Court reversed the decision of the lower court and said:

"We are without any definite information as to the speed of this car. The witnesses are of opinion that it was greater than usual, but was not so great but the motorman was able to stop it within about its length. We are not prepared to lay down any rule in regard to the rate of speed at which an electric car may be run between crossings, nor to say that the mere fact that the defendant's car was moving faster than usual at the time the plaintiff ran in front of it would be, in the language of the charge, 'sufficient to justify the jury in finding the defendant guilty of negligence.' All that can be safely said upon this subject is that the car must be kept well in hand, and that the speed must not be so great as to make this impossible, or to endanger the safety of the public using the streets with responsible care.

"But these passenger railways are created to facilitate the movements of the general public and to furnish rapid transit for citizens from their homes to the business centre of the city. They are practically indispensable in all great cities. The same rules as to speed that may be applied to ordinary vehicles propelled by horses are not applicable to street cars. They move upon a track from which they cannot turn, which is plainly visible and which is prepared with a view to the rapid movement of cars upon it. The cars can be seen and heard for considerable distances, and are required to warn persons who may be upon their tracks of their approach. The purpose of their owners and the demand of the public are that the greatest rate of speed consistent with the safety of other persons using the street or highway shall be maintained, and we are unable to say that any rate of speed that does not transcend these limits is negligence, or should be submitted to the jury as 'sufficient to justify' a verdict against the railway company.

"As to the failure to ring the bell at Fitzwater street, it is enough to say that the evidence shows that the cars stopped there only when there were passengers to get on or off at that crossing and that it was not a regular stopping place. On the day of this accident there was one to get on or off this car at that street, and there was nothing to require it to do more than slacken its speed as it crossed the street. There was no one upon the street to be warned and no occasion for striking the gong or bell. It went on with an unobstructed track before it into the next square, when suddenly this child dashed into the street just before it. The motorman saw the movement and at once applied the brake with such force as to attract attention from people who were indoors for some distance along the street and with such effect as to stop the car almost instantly. There was nothing in all this to require the striking of the gong or to suggest its necessity to the motorman. The fact that this was not done under the circumstances disclosed by the evidence in this case was not the cause of this accident nor could his failure to do so amount to negligence.

"Upon a careful examination of this record we are unable to find any evidence of negligence on the part of the defendant sufficient to justify the submission of the question to the jury. The injury was not inflicted at a crossing where the passage of footmen should be looked for. The child was upon the sidewalk until it ran suddenly on the track and was struck on the instant of reaching it. The immediate cause of the injury was, therefore, her own thoughtless act, for which the defendant is in no way responsible, and no act of negligence on the part of the motorman being shown, there can be no recovery. The assignments of error are sustained upon the facts of this case and the judgment is reversed."

VALIDITY OF LONG LIGHTING CONTRACT IN MINNESOTA.

Long-time contracts by cities for hydrants and street lights are held to be legal, in the decision by Judges Baxter and Searl, in the cases between the City of Little Falls and the local electric and water company. Several years ago, the village and city entered into contracts for water for fire protection and arc lights for street lighting for thirty years, and last year, the city attempted to set aside the contracts. The amount involved for yearly payments for both water and light is over $5,500. The judges decided that the general powers of the villages and cities give the council authority to provide fire protection and street lights in some practical manner, and that, if they decide to make long-time contracts, they have the power to do so. There was no special provision in the village or city charter providing for such contracts, and the municipality, therefore had the power to make the contracts, and once made with a company and properly accepted and carried out, the city could not annul them without being liable for damages the company might sustain. The president and principal stockholder of the company is John A. Berkey, of St. Paul, who has this and other large investments in Little Falls.

PROTEST OF WASHINGTON CITIZENS AGAINST AIR CAR.

A petition signed by residents of Brookland, D. C., has been filed with the commissioners remonstrating against the adoption of the air motor. The petitioners say they "protest against the present unsatisfactory service of the Eckington and Soldiers' Home Railway Company and the attempt to foist upon the patrons of the road an air motor that fails to give even half satisfaction. "The car," they say, "is dusty, uncomfortably warm for summer and foul smelling. It cannot make a round trip, running only from the power house to the treasury department. Consequently passengers going to Brookland are landed at the power house, where they are compelled to await the arrival of the electric car, into which they are transferred."

The petition suggests that "if an electric car accompanied each air motor as a hill horse a round trip might be made, but even that would not do away with the other disagreeable features," and that "the patrons of the road should continue protesting against being subjected to such unsatisfactory experiments when there are systems the success of which has been demonstrated and which, while entailing a greater first cost, would in the end be of profit to the company." The petition is signed by W. F. Robbins, M. L. Marean, P. M.; Grace Thomas, J. E. Eastlack and nineteen others.

THE UNION PACIFIC AND WESTERN UNION MUST SEVER THEIR BUSINESS CONNECTIONS.

After a struggle lasting two years, it has been decided that the Union Pacific Railroad Company and the Western Union Telegraph Company must separate their business connections by September 1 next. This was the order issued by Judge Munger in the United States Court at Omaha on May 24.

Counsel asked that a note be added providing for a referee to take an inventory of the property and decide to which company it belonged. They also sought to secure an amendment giving the right to present reasons why the time should be extended if new conditions arose. Judge Munger ruled this out, saying that if there were any reasons why the time should be extended they should be made known to the court before September 1, and would be passed upon.

After the case had been disposed of Judge Kelly of the Union Pacific was asked what his company would do. He said it was difficult to say. It could not appeal from this decision although it might find some way to further delay the action of the decree.

Judge Munger suggested that the question of adjusting the property right of the two corporations would be brought before Judge Cornish, special master in chancery in the Union Pacific case.

MULTIPLE SWITCHBOARD LITIGATION.—WESTERN ELECTRIC CO. vs. CAPITOL TELEPHONE AND TELEGRAPH CO., ET AL.

On June 7 the suit of the Western Electric Company, against the Capitol Telephone and Telegraph Company, of California, comes up at San Francisco before the United States Circuit Court on the argument for the granting of a preliminary injunction.

This is the first suit brought by the Western Electric Company on its multiple switchboard patents. The particular patent, which the company claims is infringed by the defendant, is that issued to Leroy B. Furman, entitled Multiple Switchboard Board, No. 252,576.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED MAY 25, 1897.

Alarms and Signals:—

ELECTRIC SIGNAL DISTRIBUTOR. P. H. Fisk, North Branch, Minn., 583,039. Filed October 28, 1895.

Details of construction.

SYSTEM OF PNEUMATIC DOORS AND GRATINGS. E. S. Corbett, Allegheny, Pa., 583,405. Filed October 29, 1891.

The movement of the door diminishes the pneumatic pressure which closes a contact of an electric circuit to sound an alarm.

ELECTRIC SIGNALING APPARATUS. A. D. Wheeler, Hyde Park, Mass., 583,423. Filed February 2, 1897.

Fire alarm system.

Batteries, Primary:—

GALVANIC ELEMENT. P. Schmidt, Berlin, Germany, 533,128. Filed May 29, 1896.

Comprises a carbon cylinder in the annular space between two zinc cylinders, the inside of the carbons containing a generating fluid, and the annular space between the carbons and the outside zinc cylinder being filled with a generating paste.

PRIMARY BATTERY. H. M. Sutton and W. L. Steele, Dallas, Tex., 583,132. Filed March 17, 1896.

Details of construction.

Batteries, Secondary:

METHOD OF AND APPARATUS FOR CHARGING STORAGE BATTERIES. C. C. Branwell, Hyde Park, Mass., 583,323. Filed August 22, 1895.

Consists in having the number of cells in the charging circuit in direct proportion to the strength of the current.

Conductors, Conduits and Insulators:—

WIRE COUPLING AND BINDING POST. J. A. Wright, Wilkinsburg, Pa., 583,242. Filed January 11, 1897.

Consists of a body, a threaded shank having a cross slot and a wire hole at right angles thereto and a screw cap provided with a central longitudinal wire hole at the end.

Dynamos and Motors:—

EMERGENCY ELECTRIC GENERATING APPARATUS. C. E. Emery, Brooklyn, N. Y., 583,173. Filed August 22, 1895.

Employs a constant potential dynamo and a prime mover for operating it and a series dynamo in parallel therewith operated by a racing prime mover.

ELECTRIC MOTOR OR DYNAMO ELECTRIC MACHINE. R. Lundell, Brooklyn, N. Y., 583,264. Filed December 15, 1896.

Comprises a field magnet consisting of two cylindrical enclosing magnetic shells having inwardly projecting wedge shaped pole-pieces and supports cast integral therewith, in combination with a single five-sided field magnet coil adapted to conform to the interior structure of the cylindrical parts when secured together.

Electro-Metallurgy —

AMALGAMATOR. F. B. Austin, Tempe, Arizona Territory, 583,354. Filed September 12, 1896.

A mercury pan formed of insulating material and provided with vertical grooves in the inner faces of its sides, and metal plates fitting the grooves of the pan and extending nearly to its bottom, the plates being provided with curved lugs.

Lamps and Appurtenances:—

ELECTRIC ARC LAMP. F. A. La Roche, New York, 583,060. Filed December 22, 1896.

Of the enclosed type.

INCANDESCENT LAMP. A. Swan, New York, 583,204. Filed December 8, 1896.

Embodies a cup-shaped base having a central conical opening narrowest at the face of the base, and a metallic shell externally grooved and located in the conical opening and held by cement filled into the conical opening surrounding the shell.

ELECTRIC LAMP HANGER. W. S. Weston, Chicago, Ill., 583,316. Filed August 8, 1896.

Details of construction.

Measurement:—

MAXIMUM AND MINIMUM RECORDING ELECTRIC METER. A. Wright, Brighton, Eng., 583,160. Filed June 12, 1896.

Consists in withdrawing from a body of liquid, portions by the action of the current characteristic and commensurate with the extreme limit thereof.

Miscellaneous:—

ELECTRIC HEEL PLATE. J. W. Gibbs, New York, 53,043. Filed January 10, 1897.

Comprises a plate element, an opposing plate element, and a non-electric generating plate to cover the rounding edge of the upper element, the latter serving also as means of supporting the person and as connecting means for the elements.

SYSTEM OF GENERATING AND USING HYDROGEN GAS AND ELECTRICITY. L. H. Wattles, Providence, R. I., 583,104. Filed December 7, 1895.

Consists in a generator in which hydrogen gas and electricity are both generated simultaneously, combining therein gas collecting apparatus having ducts for conducting the gas to mechanism intended for its use.

ELECTRIC RACE-HORSE CAROUSAL. J. W. Daniels, Paterson, N. J., 583,109. Filed October 28, 1896.

Comprises a horse mounted upon the truck with a circuit breaking mechanism or switch mounted in the mouth of the horse and adapted to be operated by means of the reins.

APPARATUS FOR AND METHOD OF STERILIZING LIQUIDS. H. G. Stiebel, Jr., St. Louis, Mo., 583,131. Filed October 2, 1896.

Consists in producing a series of disruptive electric discharges thereby generating ozone, and passing the liquid through the atmosphere of ozone thus formed and between the electrodes, but out of contact with them.

AUTOMATIC FIRE IGNITER FOR FIRE ENGINES. G. J. Brown, Chelsea, Mass., 583,208. Filed March 8, 1897.

Comprises an electric burner containing magnets, means actuated by the movement of the engine to close the circuits of the magnets and to break the circuits after the magnets have been energized.

ELECTRIC WARP STOP-MOTION FOR LOOMS. R. J. Mommers, Manchester, Conn., 583,213. Filed August 31, 1896.

Details of construction.

ELECTRIC WARP STOP-MOTION FOR LOOMS. R. J. Mommers, Manchester, Conn., 583,214. Filed August 31, 1896.

Similar to above.

ELECTRIC FURNACE AND METHOD OF OPERATING SAME. A. H. Cowles, Cleveland, Ohio, 583,249. Filed July 6, 1895.

Consists in passing an electric current and generating within the mass of the material electrical heat, and in periodically passing gas therethrough in opposite directions.

ELECTRIC FURNACE. A. H. Cowles, Cleveland, Ohio, 583,250. Filed July 6, 1895.

Similar to above.

CATHODE FOR ELECTROLYSIS. E. A. G. (called Charles) Street, Paris, France, 583,255. Filed June 13, 1896.

A thin sheet, preferably of metal, wound upon itself, for the electrolysis of bodies which produce solid deposits on the negative electrodes.

ELECTRIC GAS LIGHTING ATTACHMENT. W. H. Fargo, San Francisco, Cal., 583,303. Filed August 6, 1896.

Details of construction.

ENGINE STOP MECHANISM. J. H. Cary, Springfield, Mass., 583,326. Filed May 9, 1896.

Devices for actuating electro-mechanical apparatus located at considerable distance from the point where it is desirable to operate the same by means of electro-magnetic apparatus placed in a closed circuit.

PROCESS OF ELECTROLYSIS. E. A. Le Suer, Ottawa, Canada, 583,330. Filed April 5, 1892.

Process of decomposing the chlorids of sodium and potassium by electrolysis. Adds hydrochloric acid continually to the anode compartment.

ELECTRIC DRILL. C. E. Davis, Chicago, Ill., 583,407. Filed April 27, 1896.

Adapted for use in coal mining.

MACHINE FOR FASTENING HANGERS IN ELECTRIC WIRE CABLES. W. H. Johnston, St. Louis, Mo., and S. B. Fowler, Chicago, Ill., 583,411. Filed July 18, 1896.

Details of construction.

Railways and Appliances:—

UNDERGROUND ELECTROMAGNETIC RAILWAY SYSTEM. J. Hoffman, Schenectady, N. Y., 583,178. Filed May 13, 1896.

Details of construction.

ELECTRIC MOTOR. J. Conner, J. R. McMillan and A. J. Fuller, Philadelphia, Pa., 583,210. Filed September 26, 1896.

Truck for electric motors.

SERIES MULTIPLE CONTROLLER. T. Von Zweigbergk, Cleveland, O., 583,273. Filed January 21, 1897.

Adapted for trolley cars. Details of construction.

STREET OR STATION INDICATOR. A. C. Goetz, Cleveland, O., 583,304. Filed August 21, 1896.

Operated by current from the conductor.

OPERATING MECHANISM FOR CAR BELLS. J. T. Haskins, Malden, Mass., 583,305. Filed July 21, 1896.

A bell with two hammers operated by electricity.

BOND FOR ELECTRIC RAILWAY. J. McLaughlin, Chicago, Ill., 583,309. Filed October 19, 1896.

A connecting conductor between the heads or terminals, which is constructed of sections hinged together so as to yield in the movements of the rails.

CURRENT COLLECTING DEVICE FOR ELECTRIC RAILWAYS. W. M. Brown, Johnstown, Pa., 583,324. Filed July 18, 1896.

A magnet carried by the vehicle, a flexible member depending below each magnet pole, and a spring between, and bearing against the pole and flexible member.

Telegraphs:—

SYSTEM OF TELEGRAPHY. C. G. Burke, Brooklyn, N. Y., 583,026. Filed September 4, 1896.

A system of machine telegraphy employing the Morse code.

TELEGRAPHY. O. R. Roberson, Glen Ridge, N. J., 583,418. Filed August 24, 1896.
System of duplex telegraphy.

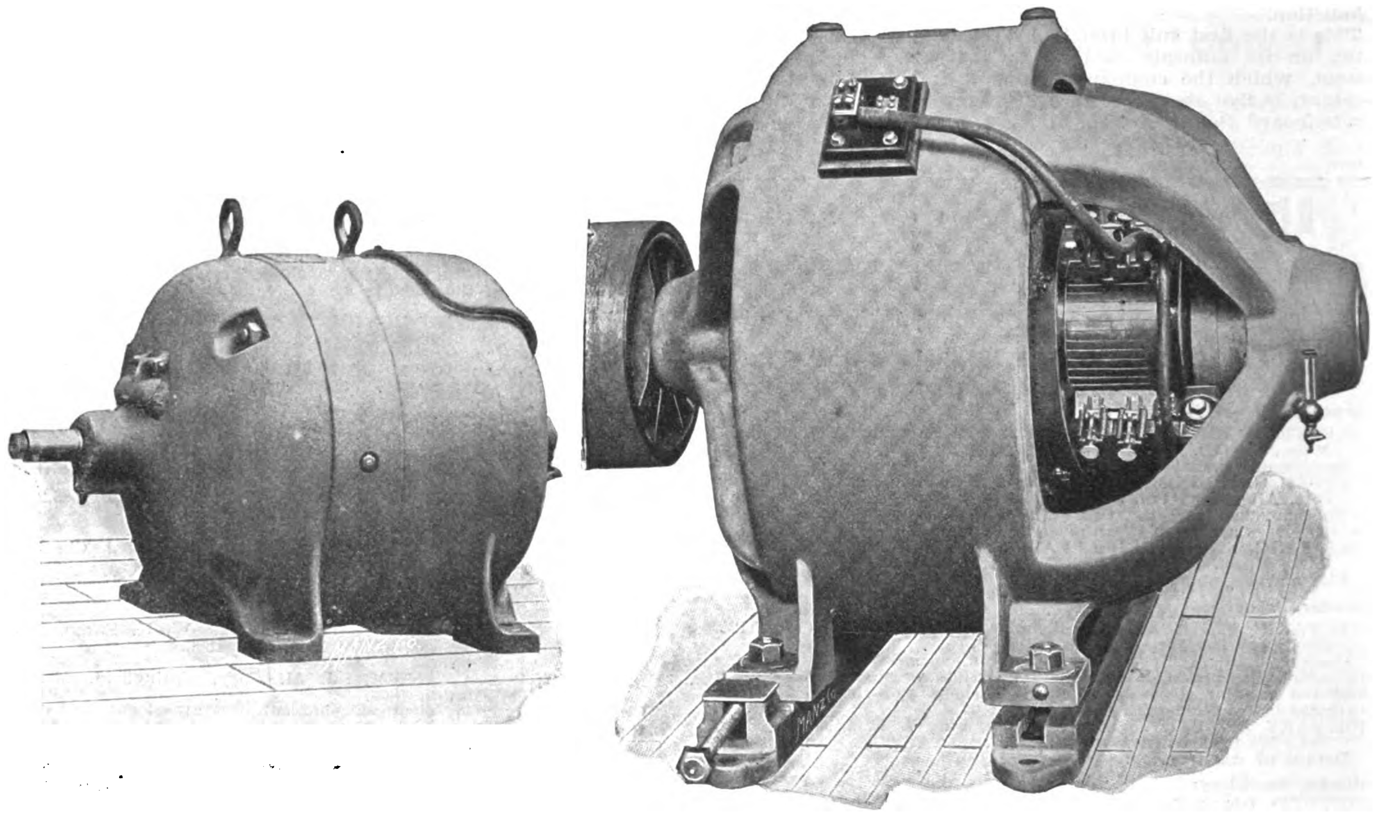
Telephones:—

TELEPHONE RECEIVER SUPPORT. L. Duque and F. M. Cosgrove, San Francisco, Cal., 583,142. Filed September 15, 1896.
A device adapted to support a telephone receiver in a natural position for a person of any height while using the telephone, so that the hands will be perfectly free for writing, etc.

NEWS AND NOTES.

THE ELWELL-PARKER MOTORS.

THE accompanying engraving, Fig. 1, shows the new enclosed railroad type intermittent service motors for cranes, hoisting machinery, isolated tools and similar kinds of service, built in sizes ranging from 2 to 60 horse-power, by the Elwell-Parker Electric Company of America, Cleveland, O. These motors are for use where there is much dirt, dust, or moisture or where for other reasons the completely enclosed type is either necessary or desirable.



FIGS. 1 AND 2.—ELWELL-PARKER ENCLOSED AND SEMI-ENCLOSED MOTORS.

Fig. 2 illustrates the semi-enclosed Elwell-Parker machine, for use in locations that do not require complete protection against dust or moisture. This type admits of somewhat heavier duty as the ventilation is better than that of the entirely enclosed machine.

The above motors embody all the latest features of modern heavy and irregular duty machines, such as self-aligning, self-oiling, removable interchangeable bearings, with ample size and rigidity of parts that are to be subjected to heavy and unusual strains.

All these machines are equipped with special carbon brushes, and are made reversible, or not, as required, and are wound series, shunt or compound, according to character of service to be performed. The armatures are ventilated and built of unusual strength. As can be readily seen these machines can be arranged to bolt to floor, ceiling beams, vertical posts, or side wall beams.

Both these types, but more especially the semi-enclosed one, are also built for continuous service for driving line shafting, isolated tools, pumps, fans, etc., and are arranged for speeds suitable for either direct, belt, or gear connection to shafts they are to drive. The efficiency of these motors is very high, and the commutators are sparkless on practically all loads.

A large number of these motors, both enclosed and semi-enclosed types, are now in use operating electric traveling cranes and ore handling machinery, and for driving line shafting, isolated shop tools, as punches, hydraulic presses, drilling machines, emery grinders, band saws, planers, etc.

The Elwell-Parker Company, of Cleveland, O., have built a number of semi-enclosed motors for operating special ore handling machinery, designed and built by the Brown Hoisting & Conveying Machine Company, of Cleveland, who have exported and erected a considerable number of these plants in Germany and Austria.

BIDS WANTED FOR RAILWAY MATERIAL.

The Riverview Electric Street Railway Company of Beaver Falls, Pa., are in the market for construction and material. Plans and specifications for the work and material can be seen at the office of H. T. Barker, the company's engineer, Beaver Falls, Pa. Bids for above work and material will close Friday, June 4, 1897, at 5 o'clock p. m. Address all bids, sealed and marked "Proposals for Street Railway," and should be sent to H. T. Barker, Beaver Falls, Pa., or J. M. Hughes, Beaver Falls, Pa.

THE STOCK MARKET

DULL BUT HOPEFUL.

Spring trade has not yet proved to be all that was expected of it, but the country is certainly not going backward the way it was two or three years ago. Merchants had been hoping for a marked gain, but the indications are that in most lines only an average demand exists, without much buoyancy. In stocks, there is also dullness, but prices are higher, and the steadily improving crop prospects encourage further advances.

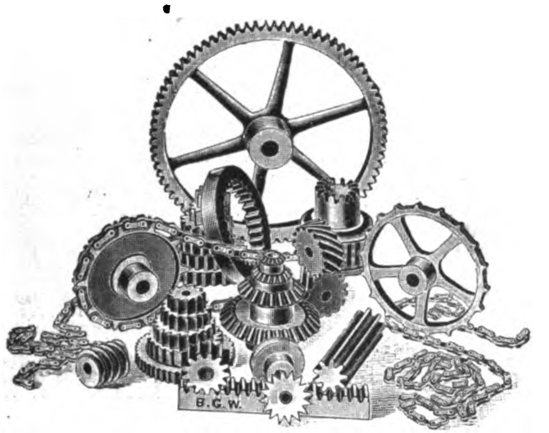
Western Union is still gaining and closed the week at around 80. General Electric was quoted at 30⅞ to 31. American Bell, in Boston, has gone off slightly to 228½, the reports of active opposition in various quarters dulling the recent demand.

COPPER. Copper is unchanged in price, and recent car-load lots of Lake were quoted at 11½ cents, Western brands at 11¼.

TRADE NOTES & NOVELTIES

THE BOSTON GEAR WORKS.

THE tendency of modern mechanics is to connect moving parts of the same machine, or machines among themselves, as rigidly and directly as possible, and hence the gear wheel is coming more and more into general use as a transmitter of motion. In many situations, of course, in which a definite and fixed ratio of speed between two moving parts must be preserved the gear is indispensable and hence the mechanic will find it useful to have some handy guide to aid him in the selection of the gear best suited for the work. We know of none better for this purpose than the catalogue of the Boston Gear Works, entitled "Gear Wheels and Cutting." This valuable booklet is not merely a categorical list of the various types of gears made by the concern, but it shows how to draw and lay out teeth for any kind of special work and how to order gears. There is scarcely a gear made that the Boston Gear Works does not carry in stock; among them we find lists of various sizes of brass and iron spur gears finished and unfinished, motor and bevel gears, standard brass ratchets and pawls, crown gears, brass racks, internal, spiral and escape wheels, elliptic gears, worm gears—in short, every conceivable type and form of metal gear for transmitting motion. Not the least interesting section is that devoted to intermittent gears, of which the works make a large variety and to which a special catalogue is devoted. Besides the gears the works also manufacture chain wheels and chains of all kinds.



SOME OF THE BOSTON GEAR WORKS PRODUCT.

The office of the Boston Gear Works, Frank Burgess, proprietor, is at 31 Hartford street, Boston, Mass., and every one building electrical apparatus, be it an electric elevator or an arc lamp, will do well to have the gear catalogues above referred to at his elbow.

BULLOCK MOTORS FOR PRESSES.

The Bullock Electric Manufacturing Company are remarkably active in the field of direct connected motor applications to printing presses, particularly of the large newspaper type, and they announce among numerous applications the following new equipments: N. Y. Herald, N. Y. Sun, N. Y. Journal (5th equipment); San Francisco Examiner, Chicago Journal, and Toronto Globe. In these equipments the motors are attached directly to the presses, and by means of the special speed regulator and starting devices the press cylinders may be inched along for making ready or run at 1-20 speed for feeding through the sheets; intermediate speeds are also given. The Bullock Electric Manufacturing Company accomplish this by using a standard motor, and the customary sources of supply, such as central stations or ordinary power circuits, the entire control coming within the movement of a single lever. The system employed is such that the enormous torque of the motor is provided for without making correspondingly heavy demand on the line.

In writing the B. E. M. Co. congratulating them on the success of their equipment, Mr. T. T. Williams, business manager of the San Francisco Chronicle, speaks as follows: I consider your motor with the slow motion attachment the only really efficient and economical method of moving a printing press. The old style of belting, while the best known up to the production of your invention, caused a loss of power at least 25 per cent. through the shaft and counter pulley; the belt was liable to slip, and it required such a long stretch of belt from the shaft to the press pulley that it was extremely difficult in many instances to set up presses in the room that could be conveniently alloted to them.

ADVERTISERS' HINTS

ARMORITE INTERIOR CONDUIT COMPANY, of Detroit, Mich., have moved to Pittsburg, Pa., where, to use their own words, they have "the most up-to-date conduit making plant in the United States."

J. B. COLT & COMPANY, 117 Nassau street, New York, furnish a complete apparatus for the manipulation of light with prism, reflectors, lenses, etc., producing scenic and illustrative effects, including the animated pictures.

THE BELKNAP MOTOR COMPANY, Portland, Me., publish this week some very excellent testimonials relative to the merits of the Chapman voltage regulator.

THE GENERAL ELECTRIC COMPANY are advertising the Wirt short-gap lightning arresters for alternating current circuits. These arresters are used on the Niagara-Buffalo transmission lines.

THE STILWELL-BIERCE & SMITH-VAILE COMPANY, Dayton, Ohio, claim there are more of their Victor turbine wheels operating dynamos than there are of any other make.

THE STANDARD AIR-BRAKE COMPANY have something to say about a progressive electric road, which publishes a time table and uses the "Standard" air-brakes.

NEW YORK NOTES.

MR. CHAS. BLIZARD, the manager of the New York office of the Electric Storage Battery Company, has moved to very handsome and commodious quarters in the new Commercial Cable building, 22 and 24 Broad street.

MR. FRANK G. FULLER, well known for years as a successful wire salesman, has associated himself with Mr. W. R. Brixey, and will hereafter devote himself to the sale of kerite wires and cables, with headquarters at 203 Broadway, New York.

VILES ELECTRIC PLANT.—One of the features of long distance power plants now appears to be F. M. Locke's porcelain insulators. In the Viles plant, illustrated in our last issue, they are used, being of the Locke triple petticoat type. The Riverside transmission in California, recently described, also employs Mr. Locke's admirable insulators.

THE CUTTER ELECTRICAL AND MANUFACTURING COMPANY, of Philadelphia, announce that they have opened an office, in charge of Mr. H. B. Kirkland, in the "Beard Building," 120 Liberty street, New York City. No stock of any kind will be carried in this office, but the extensive line of I-T-E circuit breakers and C-S switches will be on exhibition. Mr. Kirkland will be pleased to extend to his friends and the electrical trade generally the facilities of this office, and a continuance of patronage is requested. V. C. Gilpin will be associated with Mr. Kirkland.

MR. HEBER WELLS reports business in pattern letters and figures for castings as improving. This is especially the case in the brass sorts. He carries a full stock of all kinds on the corner of Ann and William streets.

McINTOSH, SEYMOUR & CO. have opened an office for the sale of their products in New York City and contiguous territory in the Havemeyer Building, Room 1211, No. 26 Cortlandt street, the Pierce & Miller Engineering Co. having ceased to handle their engines.

FULTON, N. Y.—The Victoria Paper Mills Company are making extensive additions and alterations to their plant. One of these additions will make what they term their new mill building No. 3. The walls of this addition are to be of substantial brick construction. The floors are to be carried by steel girders supported by the side walls and interior steel columns, and the roof which is to be gravel on plank will be carried by steel trusses. This will make a neat building, thoroughly fireproof, and well adapted to their needs. The contract for furnishing and erecting the steel work has been

awarded to the Berlin Iron Bridge Company, of East Berlin, Conn.

THE COOPER GENERAL MACHINE & ELECTRIC COMPANY, of New York City, has been formed, with a capital stock of $10,000, by R. Cooper, of Jersey City; C. W. Congdon, of Brooklyn, and J. H. Williams, of the same city.

THE ELECTRIC BLEACHING COMPANY.—The sheriff of New York County has received an execution against the Electric Bleaching Company for $1,520 in favor of Albert E. Woolf. The company was incorporated in March, 1892, with a capital stock of $2,000,000. T. J. Montgomery was president.

WESTERN NOTES

H. M. UNDERWOOD & COMPANY, 1114 Marquette Building, Chicago, are representing the Belknap Motor Company in that section and report that they have had a large number of inquiries regarding their voltage regulator. They have also been appointed exclusive agents for the United States for the Cloos junction box, a full description of which appeared in The Electrical Engineer of February 17. Their lamp guard is meeting with so much success that they are working overtime to supply orders and on the whole consider the business outlook for the coming season more than encouraging.

THE FAN SEASON may now be said to be fairly opened and a large business should be done during June and July. The Electric Appliance Company are in the field with a large and complete fan catalogue, showing their full line of alternating and direct current desk, wall and ceiling fans. This catalogue will be valuable to every purchaser of electric fans of any kind.

THE CENTRAL ELECTRIC COMPANY states that the fan motor business is opening up with unusual activity. The line of Lundell fan motor apparatus handled by them has been quite considerably increased this year, and with the addition of the Wagner ceiling fan motor, and the Emerson induction fan motor, they claim to have the most complete line of ventilating apparatus. Their 1897 fan motor catalogue is an unusually fine representation of the printer's art, and it will be sent to any one interested on application.

ARMORITE.—The plant formerly operated by the Pittsburg Tube Company at Pittsburg is being fitted up for occupancy by the Armorite Interior Conduit Company. Insulated pipe lined with wood for electrical conduit purposes will be manufactured.

THE EAST SIDE ELECTRIC COMPANY, Detroit, Mich., owing to an increase in their business, have ordered from the Ball Engine Company, Erie, Pa., a 100-horse-power engine. The owners of the Claus Spreckels Building, a new structure nineteen stories high, at the corner of Third and Market streets, San Francisco, have recently awarded a contract for three 150-horse-power vertical cross-compound engines, each of which is arranged for direct connection to a 100-kilowatt General Electric direct connected machine. The engines will be built by the Ball Engine Company. This will be one of the banner plants of the city.

THE WALKER COMPANY, of Cleveland, O., have just made a large shipment of 120 motors to Germany for railway work. The order was placed through Charles Le Blanc, their European representative.

DORNER & DUTTON COMPANY of Cleveland has been organized to make and deal in electrical and street railway supplies. The capital stock is $50,000. The incorporators are J. H. Van Dorn, E. J. Leighton, H. H. Hodell, W. A. Dutton and H. A. Dorner. The specialties of the company are well known.

MR. H. L. CHILDRESS, manager for the Postal Telegraph Company in Cleveland, O., has been promoted to the superintendency of the second district of the Postal Southern Division, including Alabama, Georgia, Mississippi, Louisiana, Florida and a part of Tennessee. His headquarters will be at Birmingham, Ala. He is less than thirty years of age.

H. B. CAMP & CO., Aultman, O., have received the contract for the underground conduits of the Delaware and Atlantic Telephone Company, Wilmington, Del., and will begin work on them at once.

CHICAGO LIGHTING FIXTURE COMPANY to do electric work, has been formed by H. G. Willard, J. McClellan Means, F. F. Kinney and G. G. Glaescher, with a capital stock of $25,000.

WESTERN ELECTRIC COMPANY have recently placed upon the market a soldering paste to be used in place of soldering salts. It is packed in half pound, and one pound cans.

ASTORIA, ORE.—A new electrical supply company has formed with a capital stock of $3,000 all subscribed.

NEW ENGLAND NOTES

STANDARD THERMOMETER AND ELECTRIC COMPANY, Peabody, Mass., are meeting with good success with their new Midget arc lamp for low and high tension direct current circuits. Among the concerns to which they have recently furnished their enclosed arc lamps may be mentioned the Solvay Process Company, Detroit, Mich.; Shoot-the-Shutes plant at the Nashville Exposition; New England Engineering Company, etc.

PHILADELPHIA NOTES

MR. J. F. STEVENS, Keystone Electric Instrument Company, Philadelphia, will have an exhibit in Parlor E, Cataract House, Niagara Falls, at the coming N. E. L. A. convention, and will there display a full line of their instruments, with a background of cigars and punch.

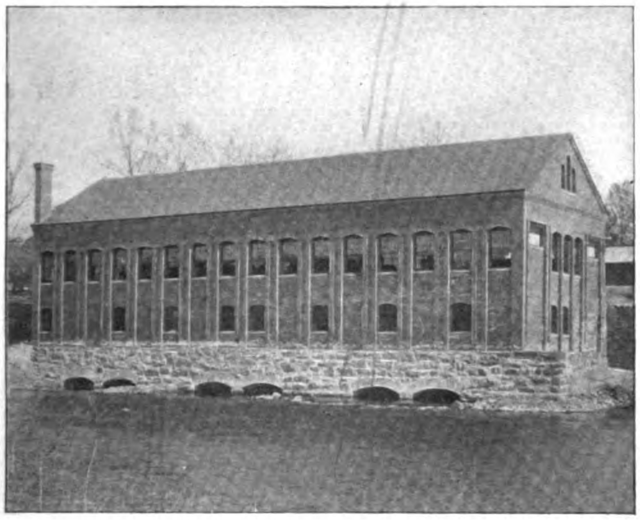
ELECTRIC LIGHTING

THE INDIAN ORCHARD WATER POWER TRANSMISSION PLANT OF THE UNITED ELECTRIC LIGHT CO., SPRINGFIELD, MASS.

SPRINGFIELD, MASS., has always been known as one of the most enterprising cities among the many which that State can boast of, and hence it came that as far back as 1881 a wideawake firm in Springfield undertook to light its premises by means of a 10-light arc machine; its neighbors soon desired to share in the benefits of the improved method of illumination and, encouraged by the results, a company, known as the Springfield Electric Light Co., was organized, to do commercial lighting. This company was later merged into the United Electric Light Co., which, since 1887 has been steadily increasing its plant situated on the bank of the Connecticut River in the heart of the city.



Indian Orchard Station, United Electric Light Co., Springfield, Mass.

It is not our intention to follow the growth and rise of the company and to describe the plant which has until recently furnished current to Springfield; but rather to give an account of the water power station which has brought about the shutting down of the company's steam plant and practically transferred its generating plant beyond the city limits. Suffice it to say that the old steam station which has not yet been dismantled contains four engines aggregating 2,000 horse power and electrical apparatus with a capacity for 23,000 incandescent lights, 1,000 arc lights, and 200 kilowatts in 500-volt motors.

Situated about six and one-half miles from the city of Springfield, is Indian Orchard, on the Chicopee River, where for many years past the river's power has been utilized for the operation of a few small mills. The availability of this power for electrical transmission to Springfield was recognized some time ago, but it was not until last year that definite steps were taken to carry out the plans which the management had long since contemplated.

THE CHOICE OF A TRANSMISSION SYSTEM.

When it was definitely decided to transmit power from Indian Orchard the most important question which came up for solution was the choice of a system of transmission. After due consideration the 2-phase system at 133 periods per second was adopted, and has been installed. As many stations probably present conditions of working similar to those existing in Springfield, it seems worth while to indicate briefly just what the management of the company considered the dominating factors that led them to the selection of the system referred to.

In the first place, they point out that the 2-phase system distributed over four wires offers two single-phase circuits entirely independent of each other, which can be run and regulated independently in case of accident to one of the circuits. Again, lighting may be done from one of the phases while a single-phase motor may be run on the other without affecting the regulation of the lights.

To these features was added the fact that the company's business is principally a lighting and not a power business and that the flexibility of the 2-phase system is a great advantage, while outside of the mere fact of a small saving in copper, the 3-phase offered no advantage over the 2-phase.

As regards the frequency of 133 periods per second, adopted, it must be borne in mind that the old station is supplied throughout with high frequency apparatus and many of the transformers and meters are designed for that frequency; it was therefore not considered advisable to break up the uniformity of the system by introducing a lower frequency for the new work. It was also shown that in the present state of the art no advantages were offered by a lower frequency with the exception of some slight bettering of regulation, but at the expense of considerable power to maintain for twenty-four hours a day a larger leakage current in the transformers. With the company's present equipment it was shown that this leakage current would amount to 75 horse power, valued at about $4,000 a year, or in a few years covering the entire original cost of the electrical plant.

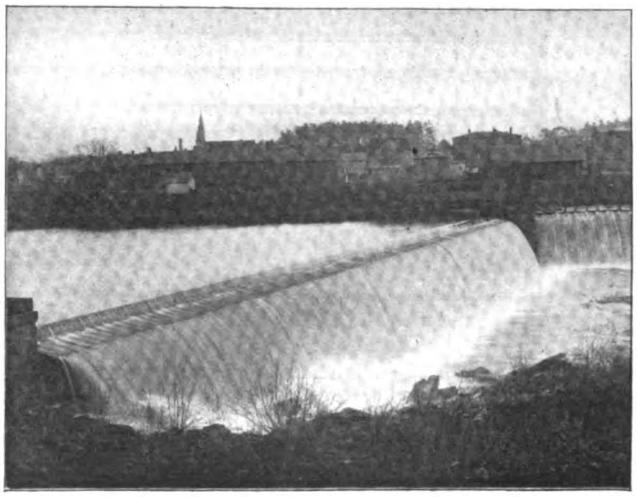
No difficulty has been found in the regulation and synchronous working, so that for this reason, as well as for those given above, the choice of the system has thus far been found to have been a wise one. Besides, if later it is deemed advisable to change to a lower periodicity, enough money, it is thought, will have been saved to make the change.

THE POWER BUILDING.

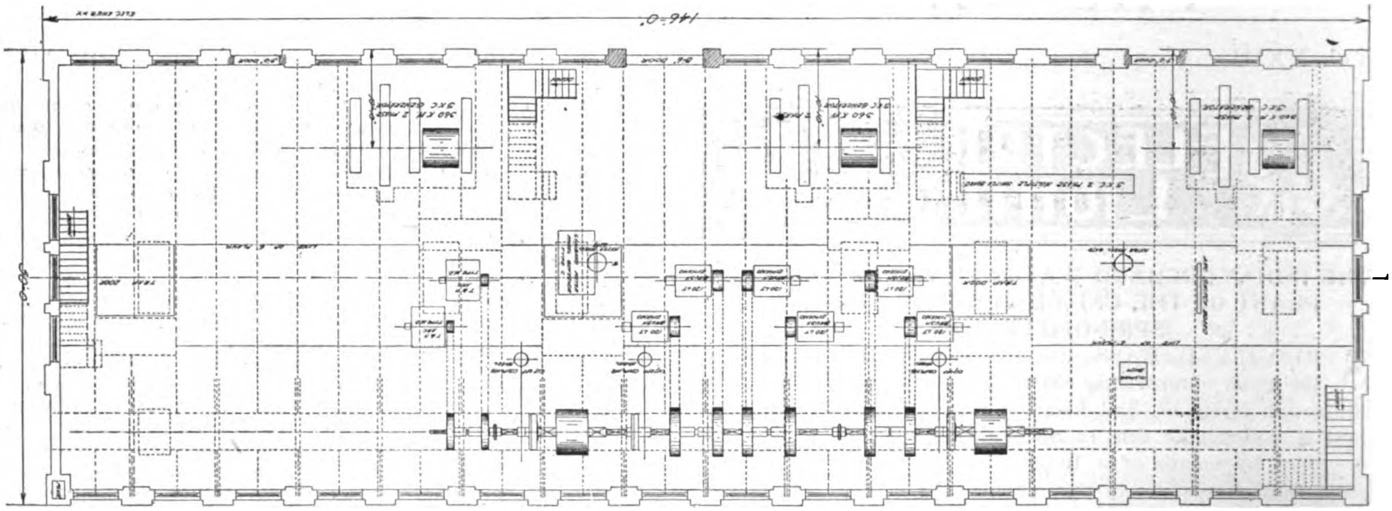
The new power building at Indian Orchard, which takes the place of a temporary installation, is shown in the engraving on this page, which gives a view of it as seen from the river.

The building, which is of brick, with massive masonry abutments, is 150 feet long and 50 feet wide. It is two stories high, the lower being occupied by the water wheels and the upper by the electrical machinery, the construction being fireproof throughout. The foundations of the building are of brown sandstone, taken from a quarry across the river directly opposite the station. The iron roof is planked with three-inch Southern pine and slated.

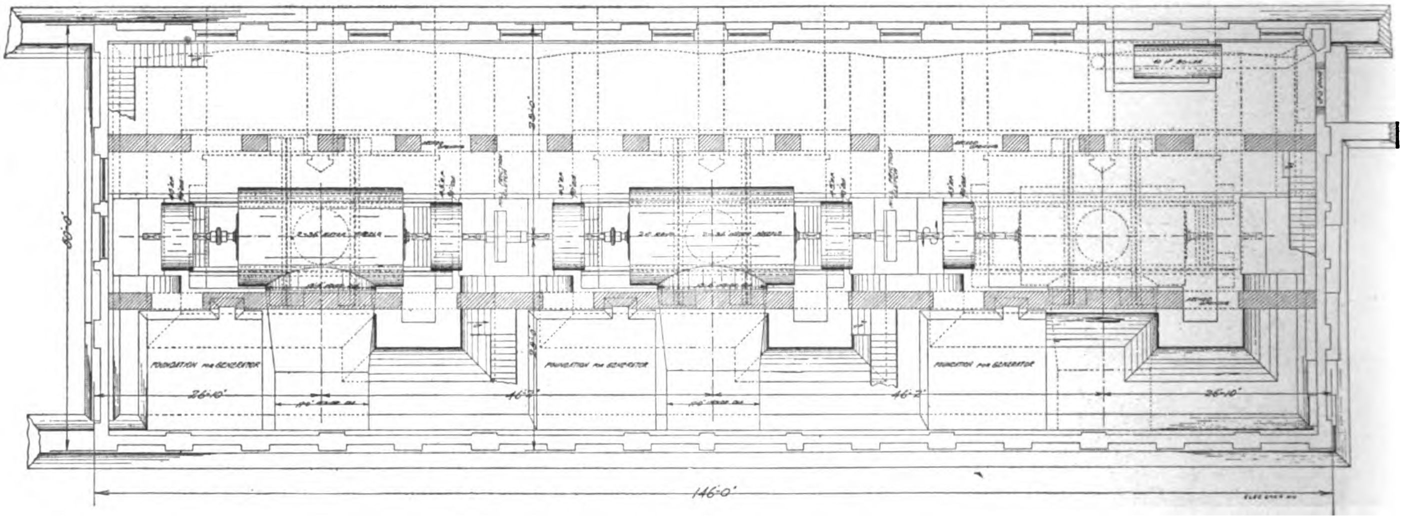
The floor is built of iron I-beams, with brick arches between them, and capped with six inches of concrete and a flooring of maple. It will be noticed that the line of countershafting is supported on a pair of steel I-beams, which run the entire length of the building. All this construction is illustrated in the cross sectional view on page 610. The traveling crane which travels the whole length of the machine room floor has a span of 45 feet, and a capacity of ten tons.



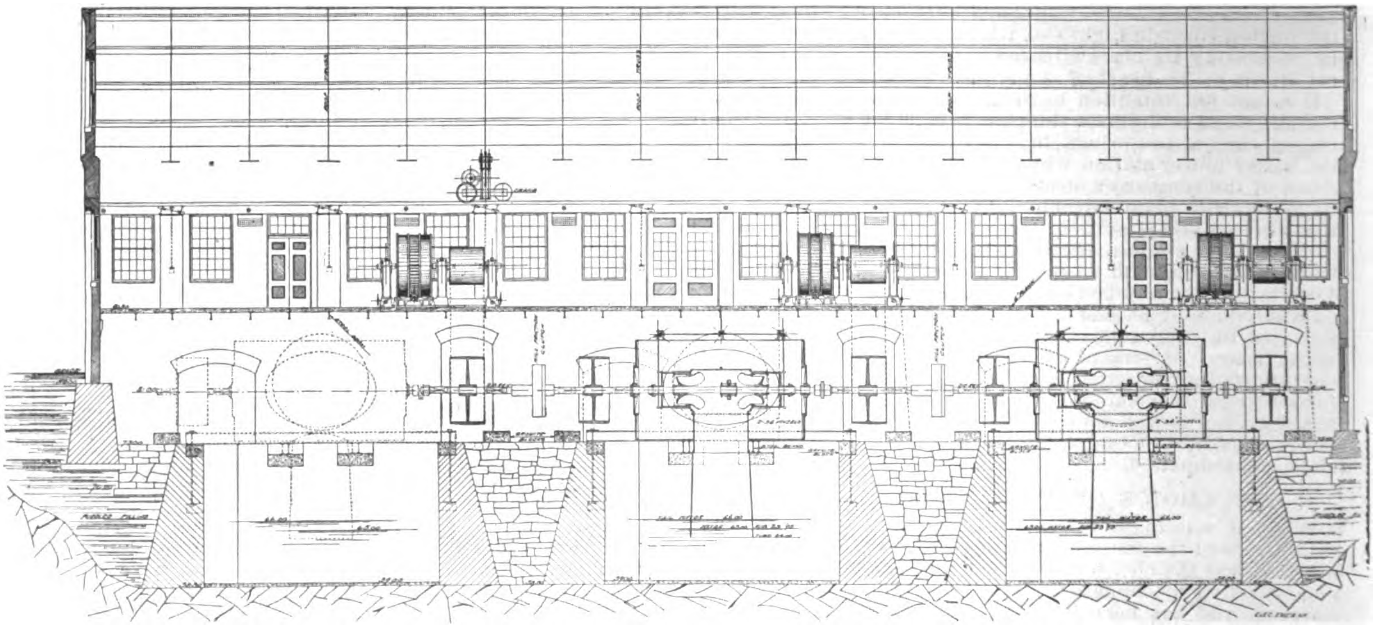
Falls of the Chicopee River, Indian Orchard, Mass.



Indian Orchard Water Power Station.—Plan of Dynamo Floor.



Indian Orchard Water Power Station.—Plan of Turbine Floor.

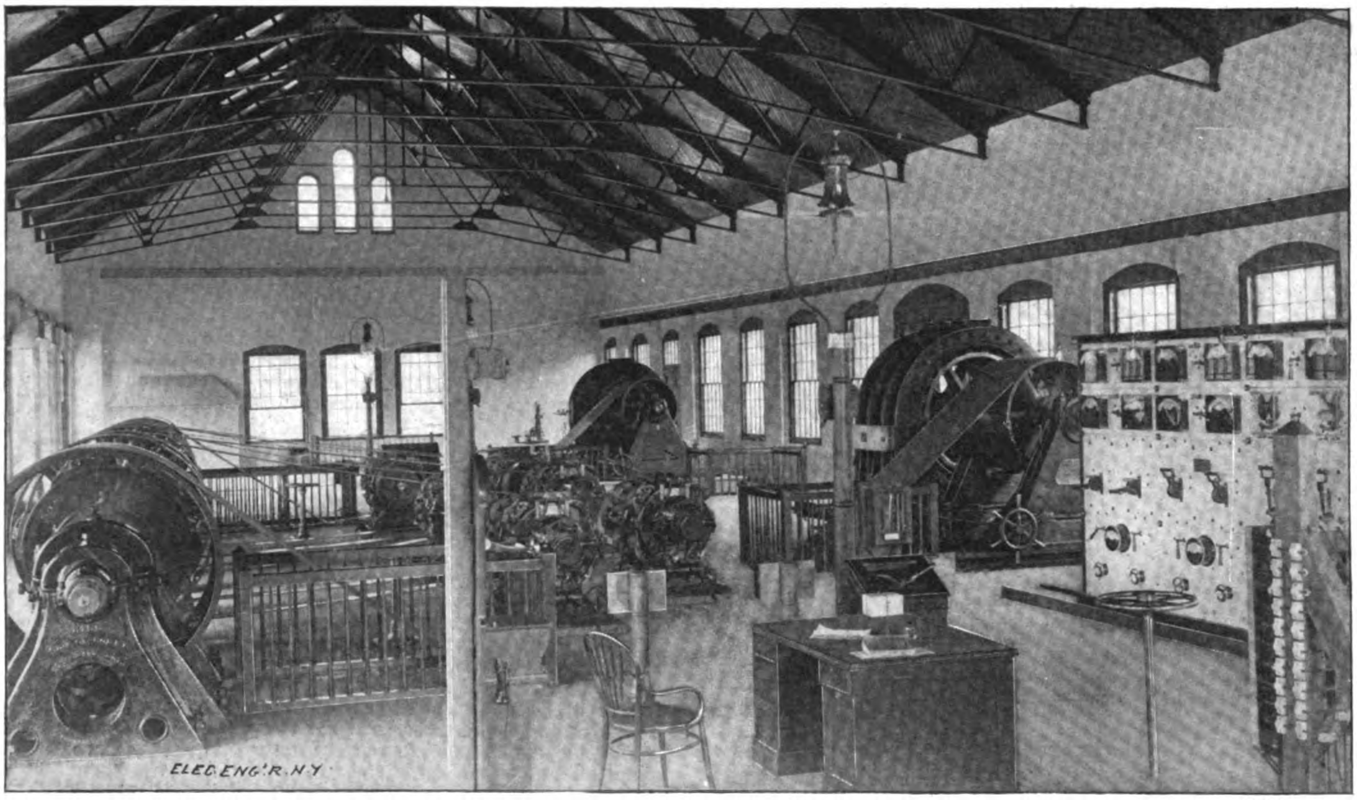


Indian Orchard Water Power Station.—Longitudinal Section Through Turbines.

THE POWER EQUIPMENT.

The stone dam 400 feet long and 26 feet high thrown across the Chicopee River has a gate house at its south end. From this gate house a canal 1,400 feet long runs in a westerly direction and at the end of the canal are the penstocks which run at right angles for a distance of 196 feet to the station on the bank of the river, so that no tail race is required. These penstocks are 11 feet in diameter and built of 7-16-inch steel, riveted and set up on saddles of brick work, 16 inches thick. Provision has been made for three head gates and penstocks, but thus far only two have been installed. The penstock cases are 11½ feet in diameter, and they, together with all iron work about the station, were furnished by P. F. Hawkins, of Springfield, Mass.

The power equipment of the station consists, at present, of two pairs of thirty-six-inch McCormick horizontal turbines, built by Jolly Bros., of Holyoke, Mass. Each member of these pairs has a capacity of 480 horse power, or 960 horse power per pair, making a total wheel capacity of 1,920 horse power. Each pair of wheels is enclosed in a case 12 feet in diameter, and runs at 210 revolutions per minute. As shown in the longitudinal sectional view on page 608, provision has been made for the installment of a third pair of turbines, when the work of the station shall demand it. These turbines can be coupled among themselves by Hill friction clutches, making one unit of power when desired. Along the wheel shaft are four pulleys, 90 inches in diameter and 45 inches face.



Dynamo Floor, Indian Orchard Water Power Station of the United Electric Light Co., Springfield, Mass.

As indicated in the sectional views, the wheels are set 15 feet above the tail water, and the draft tubes are made flaring and incline towards the river, a single draft tube being employed for each pair of wheels, which are of the central discharge type. Each wheel has two outlets, the wall between them being protected by a wedge.

The regulation of the turbines is effected by means of a Lombard water wheel governor, one of which is in use so arranged as to regulate both wheels. This governor is run in connection with a speed recorder, which gives a continuous record of the operation of the turbines. The governor is mounted on the dynamo floor and is driven by belt from the turbine shaft direct.

THE ELECTRICAL EQUIPMENT.

The plan view on page 608 shows the layout of the dynamo floor and the sectional view on page 610 shows the arrangement of the belting. As will be seen, the turbine shafts are connected by two main belts to a line of countershafting, which will eventually run the full length of one side of the building. This line of countershafting was constructed by C. F. McMurray & Co., of Troy, N. Y., and is provided with Hill clutches, which enables any machine to be run independently of the other. The bearings of this countershafting have small centrifugal pumps, the buckets of which take up oil and raise it above the level of the shaft to a reservoir, which keeps up a continuous flow of oil.

The alternating electrical equipment consists of three 360-kilowatt S. K. C. 2-phase alternators, built by the Stanley Electric Manufacturing Company, of Pittsfield, Mass. These machines run at 365 r. p. m. The voltage on each phase is between five and six thousand volts. One generator carries the day load; the two others operate 2-phase current, and are thrown in for the heavy night load. The circuits of all these machines are so arranged at the switchboard that all the machines may be run in parallel, so as to deliver their current to either of two sets of overhead circuits. We may note in passing that the No. 1 machine in this station is the first one of this size built by the Stanley Electric Manufacturing Company, now some three years ago.

The arc machines at present installed in the station are eight in number, comprising six Brush 120-lighters of the latest type, and two Thomson-Houston 75-lighters. These are arranged along the center of the floor, as shown in the plan, and belt direct to the countershaft, and can be handled independently by means of friction clutches. The arc switchboard, designed for ten circuits and ten dynamos, is mounted near the southern end of the room, and is built of marble by the General Electric Company.

THE SWITCHBOARD.

The switchboard consists of three panels, one for each generator, provided with ammeters and voltmeters on each phase of each machine. For each phase there is provided a double pole switch, designed to throw the generator on to the bus bars in parallel with any other generator. Each panel is provided with synchronizing lamps, by which the switch attendant is guided in the operation of the switches. Each panel also has a field rheostat, and a rheostat for the field of the exciting machine, and a current indicator to show the current in the field of the generator. The exciters are belted directly to the shaft of the 2-phase machines, and deliver 60 amperes at 60 volts. The field coils of the generators themselves take about 50 volts at 30 to 40 amperes.

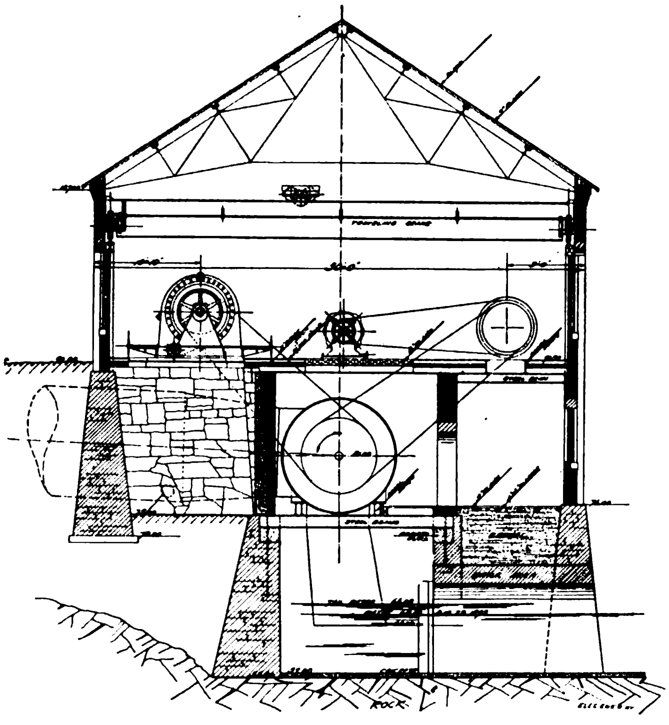
The switchboard also has two circuit panels, each panel provided for two single-phase transmission circuits, making for each panel one set of four wires for a 2-phase transmission. Each single phase circuit is provided with a current indicator and ground detector, and each side of the line is protected by an automatic circuit break switch, having eight breaks, which in case of a short circuit opens the circuit automatically. There are no fuses whatever employed on the board, reliance being had entirely on the circuit breakers. The switchboard and all its equipments was built by the Stanley Electric Manufacturing Company.

THE TRANSMISSION LINES.

From the switchboard the lines pass through marble slabs in the end wall of the building, the holes being bushed with porcelain tubes. At the point of exit the lines are provided with Wurts non-arcing lightning arresters.

The arc lines consist of seven circuits (14 wires) of No. 4 weather proof wire. These are carried on large deep-grooved glass insulators, the grooves being at the top of the insulators. Although glass has been employed in this instance for insulators with 5,000 volts alternating, no trouble has been experienced with them in the way of breakdowns or leakage after an extended period of operation.

These circuits run into the outskirts of the city and connect to the six existing arc circuits, which are used for the city and private lights. The seventh pair of wires run to the old station, and connect to the arc switchboard there, furnishing current to the day arcs. Each of these circuits carries 100 lamps and they are so arranged that in case water at the Indian Orchard station should run low the circuits can be readily connected to and fed from the old steam station.



Indian Orchard Power Station, Transverse Section.

The alternating circuits are run on the same poles with the arc circuits. They consist of two sets of four wires each, the wires being run in quadrature, so as to avoid inductive effects. These wires run to a point about one and one-half miles from the city, where they are connected to the underground conduits, which run through the city to the old station. The underground circuits consist of four duplex cables of No. 0 wire lead covered, made by the Safety Insulated Wire Company, of New York. The underground conduits are of cement lined pipe, made by the Connecticut Pipe Manufacturing Company, of New Haven, Conn.

HANDLING THE CURRENT AT THE SPRINGFIELD STATION.

At the city station in Springfield one set of the four alternating wires connects with a 2-phase S. K. C. alternator of 300 kilowatt capacity, run as a 2-phase synchronous motor. This motor drives a countershaft from which are run a 200-kilowatt 500-volt power generator, and six 75-light Thomson-Houston arc machines, designed to run the commercial circuits. The city arcs are all run directly from the Indian Orchard station.

The other set of four alternating wires are connected to two banks of three transformers, each bank consisting of two 60-kilowatt transformers, designed to transform from 5,000 down to 1,200 volts. These transformers are provided with regulating heads for cutting in or out sections of the secondary coil, for raising or lowering the secondary electromotive force. The transformers deliver their current to the switchboard at the old station in the same manner as the alternating generators did before the power was transmitted from Indian Orchard.

PLANS FOR THE FUTURE.

Although the present installation has already shown admirable results in economy of operation, the management has by no means stopped in its consideration of further possible improvements. Indeed, plans for the future are already contemplated. These include a storage battery sub-station to provide for taking the peak of the load represented by the current required for the motor circuits between the hours of three and six p. m. This is desirable for the reason that one generator at the Indian Orchard station is not of sufficient capacity to operate at the same time the power circuits and the arc lights in the early evening before the motor load goes off. The storage battery would be connected across the 500-volt motor circuit.

Besides, such a battery would always act as a temporary standby in case of the failure of current from the Indian Orchard station. It would also act as a starter for the synchronous motor, by furnishing current to the 500-volt generator run as a motor, which could be used to bring the synchronous motor up to speed.

The plan of the Indian Orchard water power station was conceived and worked out in detail by Mr. Henry S. Anderson, the able general manager of the company, Mr. F. W. Fowler, superintendent, acting as superintendent of construction. Mr. Elisha Morgan, president of the Morgan Envelope Company, of Springfield, is the president of the company, and Mr. W. A. Lincoln, of the Springfield Safe Deposit and Trust Company, is the treasurer. Great credit is due the general manager and engineers of the company for the excellent manner in which the new work has been carried out and to the officers for the liberal policy adopted by them in placing the necessary funds at the disposal of the engineers.

A LIVE WIRE "ACCIDENT" AT SYRACUSE, N. Y.

A special dispatch from Syracuse, of May 24, says: A number of lads this morning had great sport with a live electric wire at the corner of Charles and Milton avenues. The wire had been employed as a guy to support an electric light pole, but had come down and crossed a live wire in falling. The boys attached it to a piece of barbed wire from a neighbor's fence and laid the latter across the cycle path, from which wheelmen would attempt to remove it in passing and receive a shock. Another trick was to throw it over a trolley wire, making a short circuit and stopping the cars.

Martin Dinehart, a 10-year-old lad, who was playing barefooted about the corner, grasped the wire, and becoming venturesome, ran his hand swiftly across a point where the insulation had worn off. He was standing with bare feet on the tracks of a disused trolley line at the time. The boy died in about eight minutes. He had received about 2,500 volts.

MUNICIPAL PLANT CONTRACT FOR DES MOINES, IA.

McClaskey & Holcomb of Springfield, Ill., offered to furnish 500 arc electric lights to the city of Des Moines, Ia., for six and a half years at the cost of $55,000 per year, and at the end of that time to sell the plant to the city for $1. The annual payment asked for is less than the city now pays other companies for its lights, and in an election held on May 18 the proposition was accepted by a vote of nearly three to one. The city will soon vote on a proposition for municipal water works to cost $1,000,000.

KANSAS STATE IRRIGATION PLANTS A FAILURE.

A correspondent of the New York "Evening Post" writing from Kansas says: "The State is selling at auction the expensive irrigation plants that were put in last year. Some of them cost a thousand dollars each, but they are being disposed of for a song. One plant with forty acres of ground sold the other day for $158. In the work of the Irrigation Board there was seen the foolishness of putting matters of this kind into politics. The board spent $30,000 and had nothing tangible to show for it except the report, which proved that irrigation was a failure in the western portion of the State, just as everybody knew it must be." The private owners will in all probability make money out of these plants.

GLOBE BREAKING AT ROCKFORD, ILL.

The habit of globe-breaking has become so prevalent in the City of Rockford, Ill., that to protect the plant the following ordinance has just been passed: An ordinance to prevent breaking or interfering with electric light lamps, lines, poles or other apparatus.

Be It Ordained by the City Council of the City of Rockford, Ill.

Section 1. That it shall be unlawful for any person or persons to throw or cast any stone, ball or other missile or projectile at any arc lamp or glass globe thereon of the electric lighting plant of the City of Rockford, or to in any manner or by any means injure, damage, break, interfere with or destroy any glass globes, arc lamp, wire, line, pole lock fastening or other apparatus entering into the construction of or used in connection with the city electric lighting plant in the City of Rockford. Any person violating any or either of the provisions of this ordinance shall be subject to a penalty of not less than $2 nor more than $10, for each and every offense.

ARC LIGHTING FROM STREET CENTERS IN SAN FRANCISCO.

L. M. King, superintendent of the Merchants' Association, San Francisco, has recently completed an extensive report and plan for a general system of lighting this city by electricity, the additional cost of which, he claims, would not be more than $5,000 per annum. The leading principle of this system is that of suspending an arc light in the center of each crossing of all the business streets of this city and dispensing with the adjacent gas lamps, which will thereby become unnecessary. In addition to the regular business streets it is also proposed to place electric lights at each crossing on Golden Gate avenue, from Market to Devisadero, and on Folsom as far out as Nineteenth street. In this way the main thoroughfare to the Park will be well lighted and made attractive to persons driving and particularly to those riding bicycles at night. As Folsom street, from Nineteenth to Twenty-sixth, is already well lighted, this new arrangement would give Mission residents equal advantages with the rest of the city.

The cost of this system of lighting would not, in Mr. King's opinion, be more than $5,000 greater than the present gas illumination. He figures that in the district north of Market and in the Western Addition one electric light wiuld displace four gas lamps. According to the present contract these gas lamps cost 48 cents a night, and the electric light would cost 55 cents per night. The total number of electric lights required for this schedule is 281, and the number of gas lamps that would be displaced is 1,042. This would make the cost of 281 electric lights, at 55 cents each, $154.55 per night, and there would be a saving of 1,042 gas lamps, at 12 cents each, amounting to $125.04 per night, which makes the total increase of cost only $29.51 per night. These figures, however, Mr. King says can be materially reduced, and the actual additional cost would not be more than $5,000.

BRUSH PLANTS AROUND NIAGARA.

The Brush Electric Company have a large amount of electric lighting apparatus in the vicinity of Niagara Falls, which will undoubtedly be of interest to visitors to the convention.

The Brush Electric Light and Power Company of Niagara Falls was one of the first electric light companies organized in the country. They secured water power from the company that owned the canal. The property of the old Niagara Falls Brush Company was purchased a few years since by the Buffalo and Niagara Falls Electric Light and Power Company. A new station was erected very near the large power house of the Niagara Falls Power Company, from whom they secured current to run the motors which operate their dynamos. In this new electric light station may be found four 100-light 2,000-candle-power Brush arc dynamos belt driven from motors.

The Brush Electric Light Company, of Rochester, N. Y., has one of the largest arc lighting stations in the country. These Rochester and Niagara Falls companies were among the first companies in the world to operate electric lighting machinery by water power.

The Buffalo General Electric Company have a total capacity in their large arc station of about 3,000 lights. This station is located on Elk street. About one-half of these lights are run from 65-light Brush arc dynamos. The remainder of them are run from the new large Brush arc dynamos of 125 lights capacity. There are eleven of these large Brush arc dynamos.

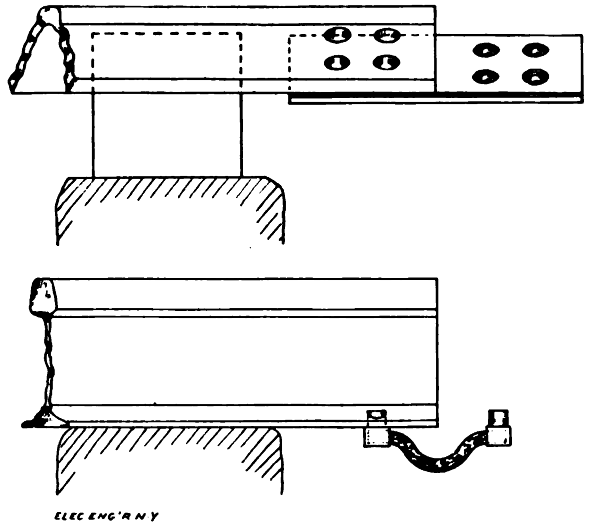
At Lockport, N. Y., there is a large amount of Brush apparatus run by water power.

ELECTRIC TRANSPORTATION

INSULATION AND BONDING OF THE THIRD-RAIL ELECTRIC CONDUCTOR.

BY H. K. LANDIS.

IN extending the electric traction system on the N. Y., N. H. & H. R. Railroad, their branch road at Nantasket Junction near Boston, the trolley construction would have necessitated a double line of poles or the spreading of the parallel tracks already in place. To avoid either of these methods it was suggested to bring the conductor down to the track and support it on the ties. Experts disagreed as to the advisability of this construction and predicted abnormal losses of current and other consequent evils. Notwithstanding the great diversity of opinion, the chief electrician of the road tried the system, which not only possesses many advantages in operation, but was installed at less than half the expense of the trolley construction already put in on the adjacent seven miles of track. Three and one-half miles were first built in the spring of 1896 and one year of operation proved so satisfactory that it was determined to put the system to a final test, to demonstrate its ability to compete with street railway traffic.



FIGS. 2 AND 3.—METHOD OF BONDING THIRD RAIL AND SERVICE RAIL, N. Y., N. H. & H. R. R.

Two tracks, one between Berlin and New Britain and the other between Hartford and New Britain, Conn., were therefore equipped with a third rail conductor, the first inspection trip being made on May 11, 1897, and the first regular service established on May 24, between New Britain and Berlin, a distance of three miles. A trolley line is under construction which will parallel this latter line, while the nine-mile division connecting with Hartford is already paralleled, and here will be decided the vital question whether the public are influenced to a very considerable extent by reduced fare and greater speed. For, on the Hartford division the experimental trips were found to occupy about twenty minutes at a fare of 10 cents, while the trolley system charged 15 cents and took fifty minutes to make the trip of nine miles. (See The Electrical Engineer of May 19, p. 535.)

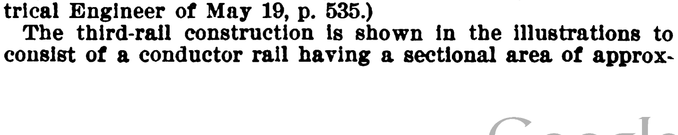


FIG. 1.—TRACK AND THIRD RAIL CONSTRUCTION, N. Y., N. H. & H. R. R.

The third-rail construction is shown in the illustrations to consist of a conductor rail having a sectional area of approximately nine inches and a weight of about 93 pounds to the yard. The service rails are the regular high carbon steel 100 pounds to the yard standard section of the New Haven road, which are 6 inches high above the ties. The top of the conductor rail is placed 1 inch higher. Throughout the track is the regular main line construction, is well graded and rides very smoothly. This is rendered necessary as the service is supposed to represent regular main line traffic, but with more frequent stops.

From the power house issue four cables, two of which connect with the conductor rail and each of the others with each of the two service rails. The latter are not insulated and are of ample conducting capacity, i. e., about equal to or slightly greater than the third rail. The conductor rail is separated from the ties by a pine block which was first creosoted, then boiled in tar, and christened the Bergtha block. The rail rests directly on this block and bonds are made between ties.

At grade crossings the conductor ends in two bare cables, each of which runs through a creosoted pine conduit 4 inches square with a bore of 2½ inches, the space between and around being filled with an insulating compound composed of petroleum residuum and asphalt mixed in such proportion as not to be pasty and yet be elastic; the whole is enclosed in creosoted inch pine board boxes from 7½ to 11½ inches square, and placed about 2 feet under the roadway. This device has given excellent results.

Under ordinary conditions the handling of a 600-volt current is attended with some risk, but in this case the conductors are so large that there seems no incentive for the current to leave them. Short circuiting is unknown in the year's experience with the third rail. By some unavoidable circumstance the Nantasket track was flooded by water for a distance of two miles and yet both the trolley line connected with the end of the third rail and the regular motor cars continued to run without being inconvenienced thereby. So much for a large conductor and low voltage.

A number of cases have occurred where workmen have received shocks from the rail but no effects ensued excepting a sharp muscular contraction. As to current deflection, there is none, and the leakage amounts to but the small amount of one per cent. One test, after a rainstorm and when the insulation on one of the cables had been broken by a spike, showed a leakage of 2.6 amperes; the cable was fused for a distance of one foot and through one-third its section. On another occasion under favorable circumstances on a dry summer evening a loss in current of 0.5 ampere was found.

The rubbing surface of the contact shoe is 12 x 5 inches; there are two of these shoes on the first car carrying the two motor trucks, and one on each trailer, connected by flexible cables. There is thus ample conducting capacity and this is probably one of the reasons why there is no sparking and so little leakage.

The standard rail bonds are of copper and are applied as illustrated. For the third rail, plain copper plates 3.75 x 12 x 1-16 inches are punched with oval holes to admit the bolts, and placed between a fish plate of the same size and the under side of the rail, then bolted in place. At crossings a brass socket plate having a contact surface of 22 square inches replaces the copper bond; it is bolted to the under side of the rail in the same manner. The cable is soldered into a socket in its end and bolt covered by the wooden approach up which the contact shoe slides to the rail end. Two of these sockets are attached to each conductor rail end and carry cables of 500,000 and sometimes 850,000 circular mils each. The capacity of the flat copper bonds is about 900,000 circular mils, and they have a sectional copper area of nearly one square inch with an additional area of two steel fish plates, each about 4 x 0.25 x 12 inches in size.

The service rail bonds are the usual copper strands the ends of which are placed in a socket and drop-forged into contact. On opening some of these contacts it was found that the connection was not as perfect as could be desired so that they will no longer be used in new work, but the bond illustrated in Fig. 3 will be used. It consists of 21 strips of copper of a total thickness of one-half inch and seven-eighths of an inch wide. The ends of these strips are placed in a casting mold and brass heads cast about them with the addition of a little solder; upon sawing through this joint the metal appears as if solid.

Contact is made with the rail through a drilled hole three-quarters of an inch in diameter into which the cylindrical split part of the bond fits; a white metal wedge is driven into this slot and the stem thus spread so as to fill the hole perfectly. This bond is flexible and when the two service rails are compared to the third rail it will be found that both possess about equal conductivity. The bonds first used had the copper strips replaced by twisted wire and the square head with stem by a flat head with circular hole for a bolt. The two first plates in the third rail joint were formerly connected, forming an angle bar joint, but this gave trouble and was abandoned.

The large cable is one inch in diameter, has 38 wires and an equivalent copper section of two-thirds of a square inch, or of one and one-third square inches at each crossing. The small cable having a diameter of 13-16 of an inch has an equivalent area for both cables of a little over three-quarters of a square inch of copper surface. The four service rail bonds carrying the return current have a total area of 1.75 square inch of copper. This is not the relative conductivity of the bonds, it must be understood, as that depends largely upon the area and character of the actual contact surfaces. The safe carrying capacity of a 500,000 circular mils cable is about 350 amperes, while the larger cable can conduct about 500 amperes.

It will therefore be readily seen that the resistances in such a circuit are very small and that when the perfection which is usually arrived at in continuous service is here attained practically all the energy sent out by the dynamo will be utilized in the car motor. The officials of the road are not yet ready to make public the exact figures referring to cost of operation, maintenance, and receipts, but say they are very well satisfied indeed with the results at Nantasket Beach.

CONDUIT RAILWAY SYSTEMS IN MEXICO.

A special dispatch from Bridgeport, Conn., of May 26, says: The American Electric Traction Company, which was recently formed in New York for the purpose of placing the third-rail scheme of Capt. J. M. Murphy into operation, has secured several contracts, which guarantee its success, among them one with President Diaz of Mexico, and J. B. Higgins of California. This contract was made for the patent right in Mexico and in return President Diaz agrees to compel by law all overhead systems to bury their wires and further agrees to have in practical operation, within a period of six months, a road out of the City of Mexico equipped with Murphy's system.

TROLLEY AND STEAM COMPETITION IN OHIO.

The Lake Shore & Michigan Southern has reduced passenger rates between Cleveland and Painesville and Cleveland and Elyria to about 1½ cents a mile, to compete with the electric roads. This low rate can be had only by buying 25 rides at once, however. A Cleveland paper says that the rate is a trifle lower than by the electric line; and the speed is considerably better.

THE STEAM AND TROLLEY SITUATION IN CONNECTICUT.

The defeat of the projected trolley parallel between Norwich and New London ends the contest for the session of steam and trolley in the Connecticut Legislature, and there are no more noteworthy questions relating to parallel trolleys to be disposed of. An analysis of the results, so far as concerns trolley roads, shows that under new charters or amendments of old ones about 151 miles of new trolley roads have been authorized. Of that number about fifty-seven miles represent trolley roads very unlikely to be built, or, if built at all, a long time hence. About eighty-three miles are parallels of steam roads, and of these about twenty miles—including, in one case, parts previously built—are now under construction. On two roads or extensions the State courts will probably have to pass under the "necessity and convenience" clause of the general street railroad law. Prospectively at the end of the present year from seventy-five to one hundred miles will have been added to the mileage—about 350—in operation in Connecticut on January 1, 1897. Of the projected trolley parallels, however, some twenty miles are very indirect parallels, and do not seriously menace steam-passenger traffic. On the whole, the steam interests have emerged from the legislative campaign pretty successfully. As a concession to public demands and from motives of policy they have been forced to yield two important parallels—the Hartford and New Britain and the Torrington and Winchester. But the former has been met by the third-rail route and the latter is a localized line. On the other hand, the steam interests have defeated trolley projects for serious parallels between Derby and New Haven, between Norwich and New London, and, probably, in the courts, between Streeton and Stratford. An important parallel trolley link between Southport and Westford yet remains to be passed upon by the courts.

TORONTO, CANADA, for the third time, has voted on the Sunday street car question, and this time the clergy and their allies in the livery business have been downed, the vote in favor of Sunday cars being 16,433 against 15,954. The preceding polls were against Sunday service by 2,000 votes first and next by only 900.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—XIII.

BY JOSEPH APPLETON. (Copyright, 1897.)

STORAGE BATTERIES IN EDISON STATIONS.—Continued.

IT is found by the Boston Edison Company that the batteries can be charged most conveniently and economically at night. By means of the tie lines all the load on the system can be carried from one station and this, together with the current used for charging the batteries, forms a total load which is sufficient to secure efficient operation.

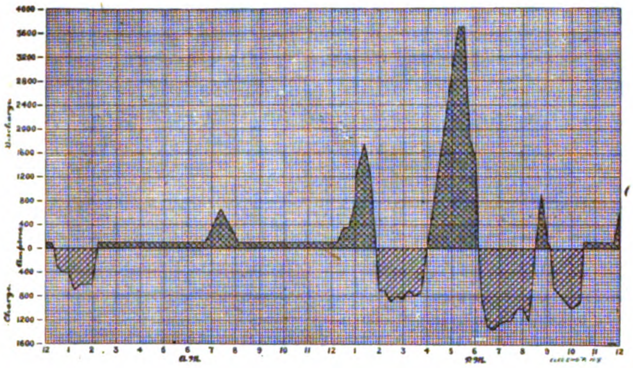

FIG. 49.

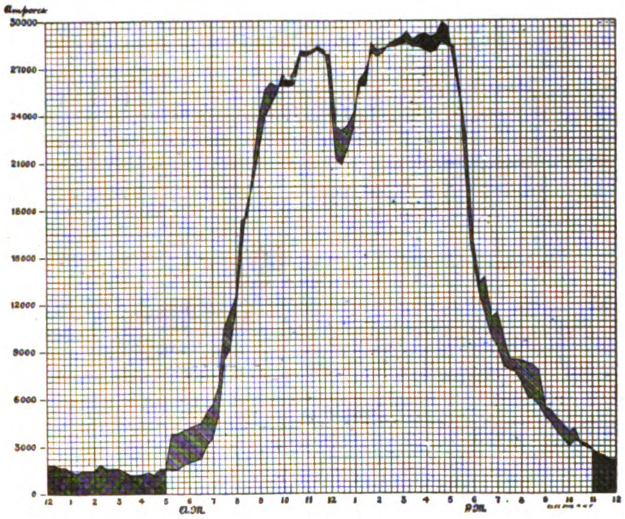

FIG. 50.—CURVE SHOWING LOAD AT DUANE ST. STATION OF NEW YORK EDISON CO., AND THE PORTION OF SAME CARRIED BY STORAGE BATTERIES.

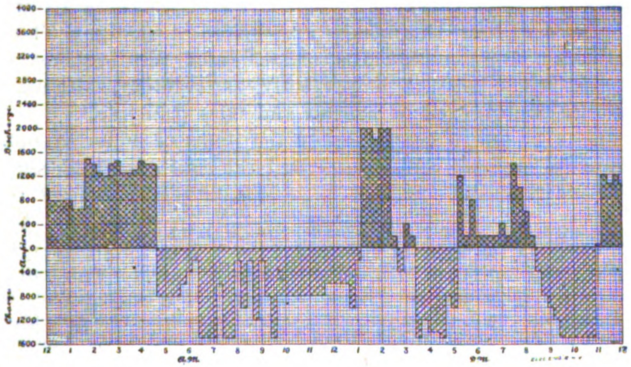

FIG. 51.

The New York Edison Illuminating Company have three storage battery plants in operation. The first installed is located at one of their uptown stations on Fifty-third street. It has a capacity of 1,000 amperes for three hours, or 2,000 amperes for one hour.

The second battery is in the Twelfth street station, which is located practically at the center of the area covered by their system. This plant consists of 150 cells, having a total capacity of 800 amperes for ten hours, or 2,000 amperes for three hours, or 4,000 amperes for one hour.

Both these batteries act as auxiliaries to the stations in which they are installed, but the third battery is located in a sub-station which forms the center of distribution for a portion of the downtown district, and is used both for this purpose and as an auxiliary to the large Duane street station.

This battery consists of 150 cells having a total capacity of 800 amperes for ten hours, or 2,000 amperes for three hours, or 4,000 amperes for one hour. It is located in the Bowling Green Building, about one mile from the Duane street station, and takes the place of an annex generating station, formerly situated in the Produce Exchange.

The battery is charged from the Duane street station at times of light load through tie lines which are arranged so that they can be used as feeders on the system during the hours of maximum load, feeding current into the system from both the Duane street station and Bowling Green battery; this

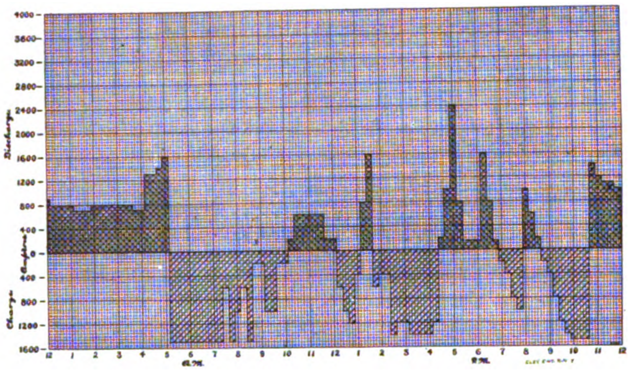

FIG. 52.

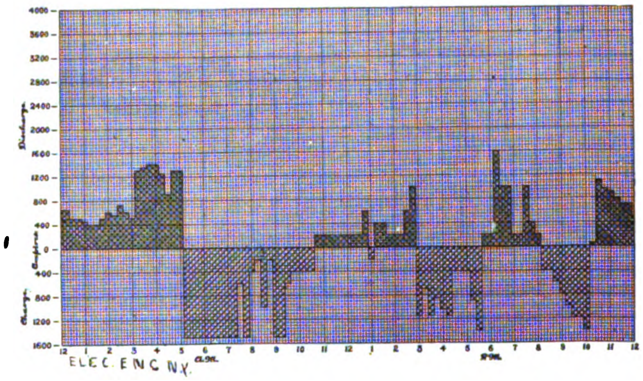

FIG. 53.

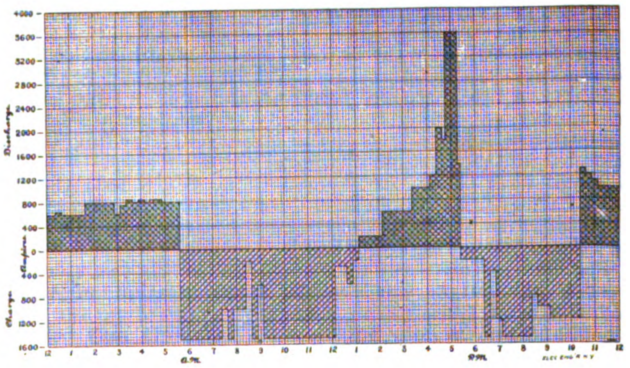

FIG. 54.

saves considerable in the copper required for the distribution of the current in this section.

Fig. 49 is a diagram of the work done by the Twelfth street battery during 24 hours. This battery being situated at the center of the system enables the various generating plants to be run at the most economical point, the surplus current from any one being used for charging the battery, and vice-versa the battery assisting any of the stations when required. It also carries the peak of the load for the immediate district, thus obviating the necessity of transmitting this large amount of current over the feeders from one of the other stations at a time when the loss would be the greatest and the value of the current at its maximum.

Fig. 50 illustrates the load curve of the large Duane street station, and shows how the Twelfth street and Bowling Green batteries enable the entire generating plant to be shut down during the night, as well as the assistance they give in equalizing the load on the generating units during the day time. The discharge is represented by the double shading and the charge by the single shading.

Figs. 51, 52, 53 and 54 show the working of the Bowling Green battery for four days and illustrates the flexibility which such an arrangement gives; the battery being constantly called upon to discharge and assist the generators or take up surplus current as the conditions demand, thus enabling the generating plant to be operated in the most efficient way.

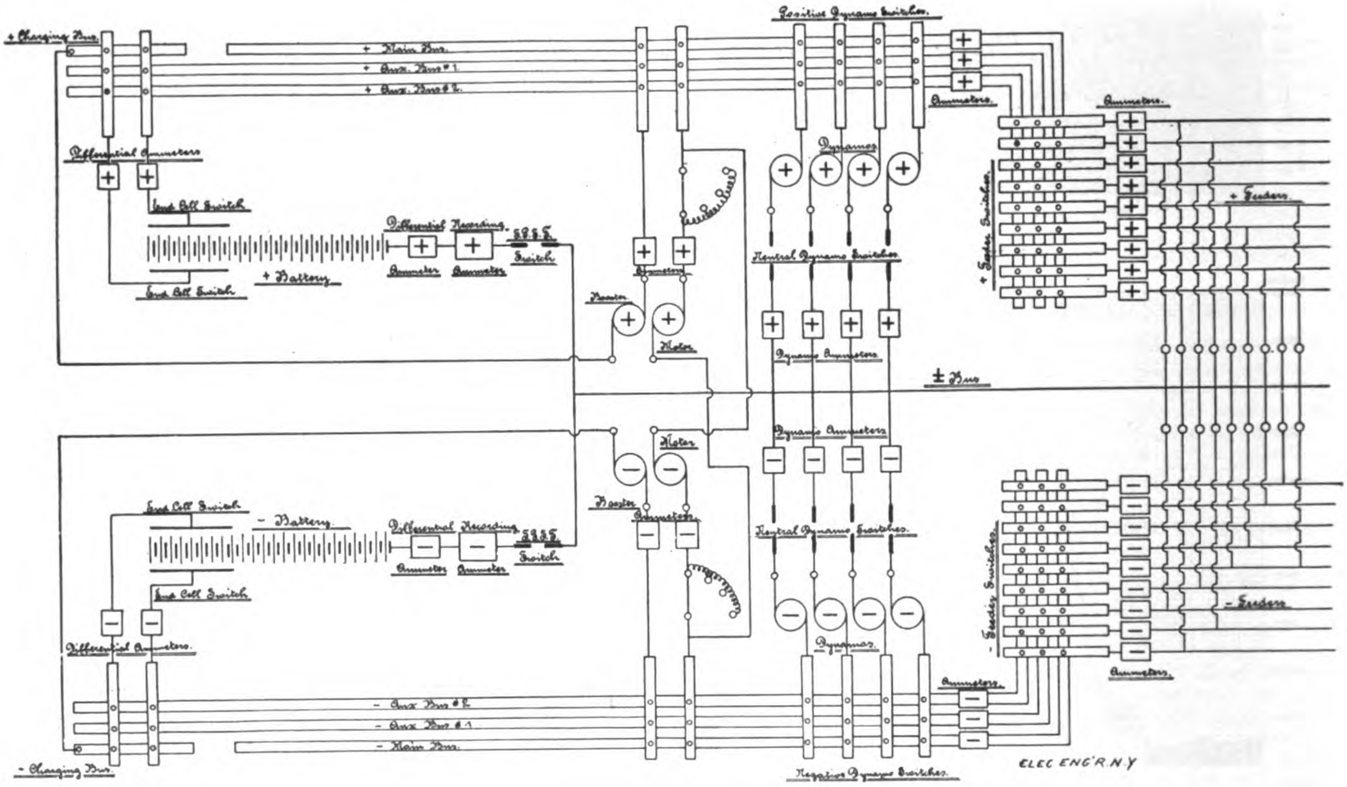

Fig. 55.—Diagram of Connections of Storage Battery in 12th St. Station, New York Edison Co.

Fig. 54 shows how the battery is of great assistance in times of emergency, such as a thunderstorm. About five o'clock on this day, a thunderstorm came up and the load increased tremendously, exceeding the capacity of the generating plant by several thousand amperes; the battery at Bowling Green responded and discharged at the rate of 3,600 amperes for about one-half hour while the excessive load continued. The value of a battery under these conditions cannot be overestimated; it frequently prevents the pressure dropping on the whole system if not a total shut down.

Fig. 55 illustrates the method of connecting the storage battery equipment at the Twelfth street station of the New York Edison Illuminating Company. The diagram explains itself and shows how flexible such a system may be made.

CATALOGUES AND QUOTATIONS WANTED.

The city of Okolona, Miss., is just completing a system of water works and electric lights, and Abbott, Glidewell & Company, hardware merchants, of that place, wish to get catalogues, quotations, etc., on apparatus of this class.

LETTERS TO THE EDITOR

GAS ENGINES FOR ELECTRIC LIGHTING.

THE editorial in The Electrical Engineer of May 26 on the experience had with gas engines in an English central station has been read with interest, and the writer has thought that a brief account of his own experience with those engines would be of value to the Engineer's readers.

We have had a 50 horse-power "Otto" gas engine in use in our electric plant for 7 years, and are installing a second 50 horse-power engine of the same make and intend installing a third in the near future, making 150 horse-power in all.

We have been using a 50 horse-power Westinghouse "Standard" along with the 50 horse-power Otto, the two being belted to a line shaft carrying a balance wheel weighing about 3,000 pounds. From this shaft are belted a 50-light Thomson-Houston arc machine and a 1,000-light Westinghouse alternator. The service is perfectly satisfactory, although the engine is governed on the hit and miss principle.

Leaving out of consideration the items of boiler attendance, repairs, etc., we have found that the coal gas at 30 cents per thousand is equal to coal at $2 per ton. In this connection I might mention that our engines are of the older type and use at least 20 per cent. more gas than more modern engines.

With us the cost of lubrication is a very small item, as we use about 3 pints of filtered oil (from dynamos), 1 pint cylinder oil and ½ pound of grease for an 8-hour run. This would make the cost of lubrication less than 0.1 cent per kilowatt hour. The ignition tubes cost 1¾ cents per day. The repairs amount to about $50 per year on the average, or about 1-10 of a cent per kilowatt hour.

I consider that any company operating both coal gas works and electric plant will be largely benefitted by using gas engines.

Standard Electric Light and Power Apparatus, 1897.

INTRODUCTION.

IT was in 1831 that Faraday discovered the great and simple principles of magneto-electric induction. That discovery was soon followed by the construction of machines for generating electric currents, and beginning as early as 1833 we find the magneto machines of Paxton, Clarke, Holmes, Van Malderen and a host of others rapidly following one another, each an improvement in some respects upon its predecessor. Then came Siemens and Wheatstone with the great discovery of the dynamo principle of self-excitation which did away at one stroke with the greatest obstacle that had stood in the way of constructing powerful electric generators. Gramme showed how the Pacinotti ring could be utilized as a generator armature as well as for that of a motor. The Siemens and Gramme may be said to be the prototypes of all dynamo machines at present constructed.

As regards electric motors, their history is almost coeval with that of the magneto and dynamo electric machine, but it was not until Gramme in 1873 demonstrated the reversibility of his dynamo that the electric motor really began to occupy a recognized position as a factor in power transmission, and it practically took ten years before that recognition was sufficiently grounded to enable the electric motor to obtain a commercial foothold.

The dynamo and motor made possible those applications which created new industries that are still the wonder and admiration of the world and whose influence has yet scarcely begun to be felt, great though it has been. The dynamo and motor made possible the arc and incandescent light, the electric railway, the electric heater, the purest, refined electrolytic copper, the electric furnace and all its products present and still to come, the great transmissions of power of which Niagara stands at the head—and a host of others too numerous to mention.

In view of the far-reaching importance which electrical apparatus has assumed it has been thought that a brief description of the principal types as now constructed by various American manufacturers would be of timely interest.

The apparatus described below, though fully representative, is by no means complete, it being impossible to gather within the limited space at command the work of hundreds of manufacturers. But such as it is it will not fail to show the trend of modern practice and may, it is hoped, prove instructive to the student, the user, and the manufacturer as well.

I.—DIRECT CURRENT DYNAMOS AND MOTORS.

THOUGH at one time quite a sharp line was drawn between the motor and the dynamo, that distinction has long ceased to exist, and hence we have grouped both under the same general heading. The abolition of this distinction was due largely to the improvement in the design of these machines and one hears nothing nowadays of the lead of the brushes, that never-ending topic of discussion of the early days of dynamo machinery. The carbon brush has also come into general use and has added much to the life and running stability of the machine. The commutator still exists, though it has lost many of its terrors, while hope is still held out to us by several workers for a commutatorless dynamo.

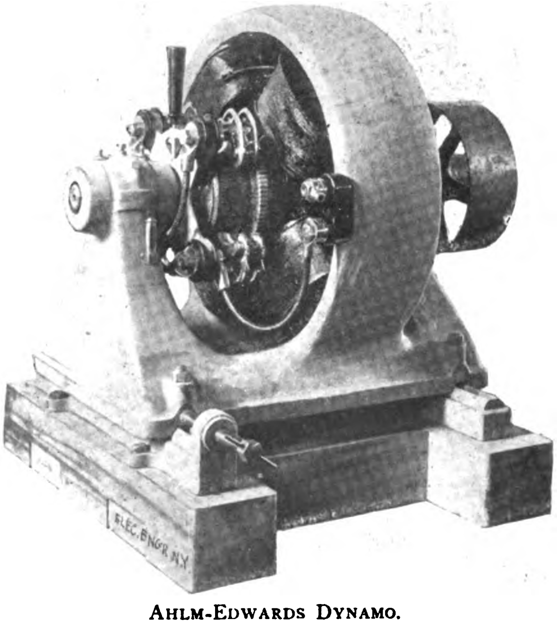
THE AHLM-EDWARDS ELEC. CO., CLEVELAND, OHIO.

The magnet yoke of these machines is one single casting for machines up to 20 kilowatts and divided horizontally for machines above 20 kilowatts, and provided with a base cast thereto. The magnet yoke is made of the best cast iron and is of the multipolar type with projecting poles. The bearings are of the ball, socket and self-oiling type, with babbited linings.

The magnet poles are laminated, of wrought iron, and cast solidly with the magnet yoke, making a welded and perfect joint with the same. The polar surface is increased by the use of pole shoes designed and shaped so as to maintain under all conditions a steady commutation point.

The magnet coils are wound on well insulated sheet iron spools with brass flanges, having the terminals of the winding brought out in a manner proper to avoid danger of breaking in handling.

The armature is of the toothed drum type and built up of thin double annealed sheet iron discs securely attached to the shaft by means of a cast iron spider. All armature coils are interchangeable.



AHLM-EDWARDS DYNAMO.

The commutator bars are of hard drawn, drop forged copper of 9-16 inch wearing depth and insulated from each other by .03 inch of the best India mica.

22	70	475	28	12	84x62 in.
33	100	425	36	14	93x65 in.

BULLOCK ELECTRIC MFG. CO. have brought out a complete line of 1897 generators and motors for direct current from 1 kilowatt to 150 kilowatts, both for belted and direct connected work. The shop tests require non-sparking with fixed brushes under an instantaneous variation of from 50 per cent. overload to no load, and vice versa.

The pole pieces of these machines are of laminated wrought iron, cast into the annular fields. In compounding, the series coils are independent and separated from the shunt coils, so that a circulation of air is permitted between them as well as through the pole pieces. The armatures are of the iron clad type, the laminae being of unusually thin charcoal iron. Wooden retaining wedges are used for the coils, which are of the continuous conductor type. Armatures are thoroughly ventilated, down to the smallest sizes. Radial carbon brushes are used almost exclusively, each brush having its own adjustment. In the case of the larger machines the brush holders are supported from the pole pieces.

In addition to their standard apparatus the Bullock Co. have produced a complete line of direct connected iron clad motors for all classes of work, beginning with 1 horse power at 100 revolutions per minute, and ranging upward.

C. & C. ELECTRIC CO.—The illustration represents this company's new six-pole generator. The armature coils are form-wound, the slots being separately insulated with fireproof insulation. The field coils are reinforced for protection, and are interchangeable. The air gap is sufficiently small to avoid the necessity of large magnetizing currents, and the flux densities determined with a special view to sparkless commutation. In this respect the results are very flattering. The 60-kilowatt machine was loaded up to 75 kilowatts and ran several hours at that load with practically no sparking, and without shifting the brushes. The net commercial efficiency of the C. & C. six-pole direct connected dynamo is 92 or 93 per cent. at full load, in the larger sizes, and careful tests show a falling off of only 3½ per cent. at one-half load. An efficiency curve taken from a 60-kilowatt C. & C. direct connected generator showed a net commercial efficiency of 80 per cent. at ¼ load. A full description of this machine appeared in The Electrical Engineer of May 26, 1897.

CARD ELECTRIC CO.—This company's machines have their field cores cast in one piece and all details have been worked out with great care. They are built in standard sizes up to 85 kilowatts as generators, and 125 horse power in motors, for 125, 250 and 550 volts.

CROCKER-WHEELER ELECTRIC CO.—The engraving represents this company's new type low speed motor for direct connection. The machine shown is the size 2-100, called so because at 100 revolutions per minute it gives 2 horse power. This method of rating is adopted because the motor is intended to be wound for any desired speed and will give power corresponding to the speed. The requirements of a very slow speed motor which shall be efficient, have been carefully considered, every point in favor of a slow speed motor having been taken advantage of, so that many features of the machine are novel. The size illustrated of this new line of machines, is about 30 inches in diameter over all and perfectly round, resembling a fly wheel and especially proportioned for direct bolting flat against the machinery to be driven, from which it will project about twelve inches over all.

It is an eight-pole machine with wrought iron cores, cast iron yoke and detachable pole pieces. The metal of the yoke is carried over the sides and forms a curtain or protection for the coils, at the same time giving great rigidity to the frame and adding to the appearance of the machine. It also forms a continuous "lug" by which the motor may be bolted at any point to different kinds of machinery. The armatures are of the toothed iron clad type supported on solid cast iron spiders and wound with separately formed coils.

Cables for connecting the various brush holders are made unnecessary, the brush holder stubs being directly attached to brass conducting rings which are entirely covered with insulation. These rings are bolted together and rock in rollers bearing on the extremities of three brass brackets, the bearing extremities of the brackets being bored to a true circle from shaft center. The free ends of the brush holder studs point outward, and being unobstructed, the brush holders may be slipped bodily off from them and the surfaces of contact of the brushes with the commutator may be readily seen.

The type chosen for this machine is such that the efficiency is the highest that can be obtained at the low speed. By special means of regulation, the speed of these machines can be varied, the changes being accomplished without resistances. These machines can be run at half speed with full torque and full efficiency. They are designed so as to stand a very high temporary overload.

A number of new features have been incorporated in the design and construction of the latest type of Crocker-Wheeler direct connected generators. The frame of the machine is of cast steel, to which the pole pieces, also of cast steel, are bolted. A ring type armature with a drum winding is used. This winding is firmly secured at each end by means of thoroughly insulated clamps, which prevent any displacement of the winding and protect it from damage.

The armature core is built up of soft laminated iron discs insulated with paper and the tooth is of the overhanging pattern. The winding is threaded through the slots in the armature, which makes it practically iron clad. The core is supported on the shaft by means of a split collar, and drawn up to a bearing with bolts. The commutator is of ample capacity and the connections to it are made with set screws held in position with cotter pins.

The rocker arm consists of two rings supported from the frame of the machine, making it self-contained. The rings are thoroughly insulated from each other and an allowance is made for the adjustment of the brushes. The brush holders are connected to one another by a series of insulated links which enable them to be lifted from the commutator by the movement of a small lever placed on the side of the rocker arm. Carbon brushes are used and are held by an adjustable brush holder of the most improved design.

The Crocker-Wheeler Company is now making these machines in ten sizes, viz.: 6, 9, 15, 30, 50, 75, 100, 150, 200 and 250 kilowatts capacity.

DIEHL MANUFACTURING CO.—The principle on which the Diehl motors and dynamos are constructed is that of the armature encircling and revolving around the field magnets. The slower speed thus gained is due to the large diameter of the armature, and is obtained without increase of weight, and gives a starting torque proportionately great; at the same time increasing the efficiency by a diminution of friction of the bearings and the brushes.

The armature, which is of the ring type, is securely housed within a brass casing, which not only protects it from mechanical injury, but also acts as a balance wheel for the machine, and further presents a large radiating surface which carries away the heat generated in the armature.

Perfect lubrication of the bearings is obtained by means of reservoirs in the standards, which are cast hollow. The amount of oil in the reservoir is indicated by the height of oil in the glass gauges on the sides of the standards. The bronze bearings in which the shaft rotates, are so formed that they rest in spherical seats of babbitt metal formed in the standards, and allow of a perfect alignment of the shaft.

The following table gives the data of the Diehl machines, which are wound for any direct current up to 500 volts:

TABLE OF DIEHL MOTORS AND DYNAMOS.

H. P.	Approx. Speed.	Pulley Diameter.	Pulley Face.	Weight.	Floor Space.

The speed of dynamos and motors wound for 500 volts, is 10 per cent. higher than the speed given above.

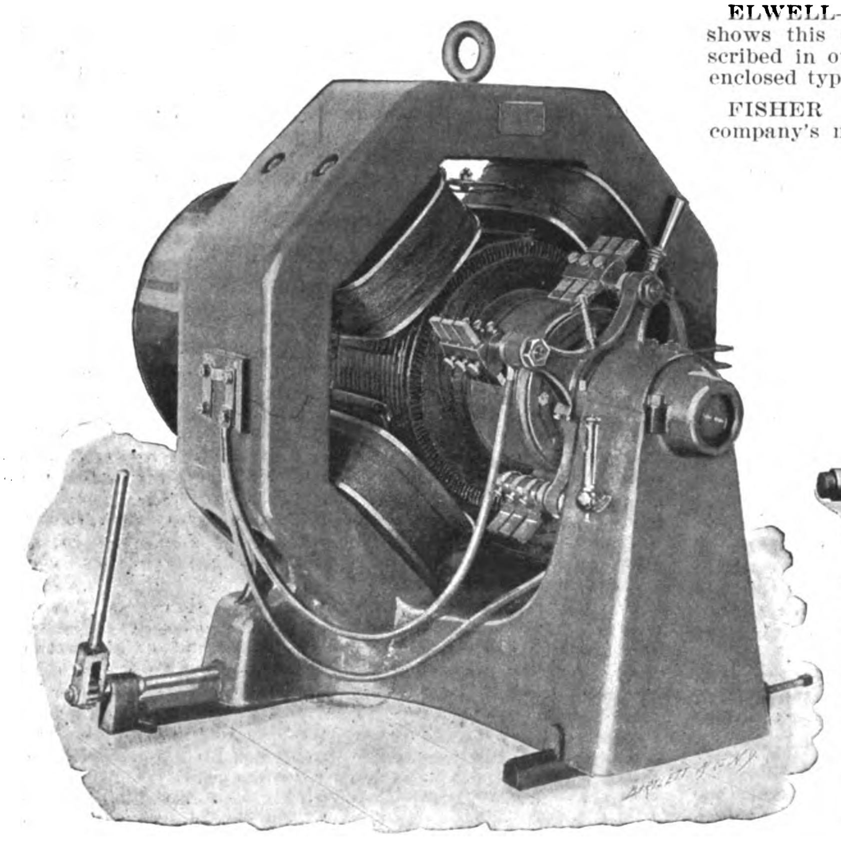
ELEKTRON MFG. CO.—This company's dynamo, illustrated herewith, is built in sizes from 18 kilowatts upwards, the machine illustrated being of 25 kilowatts.

The field magnet is a steel casting with the four inwardly projecting poles cast integral with the ring. The field coils are machine wound and are slipped on the pole pieces from which they are separated by a small air space, insuring cool running.

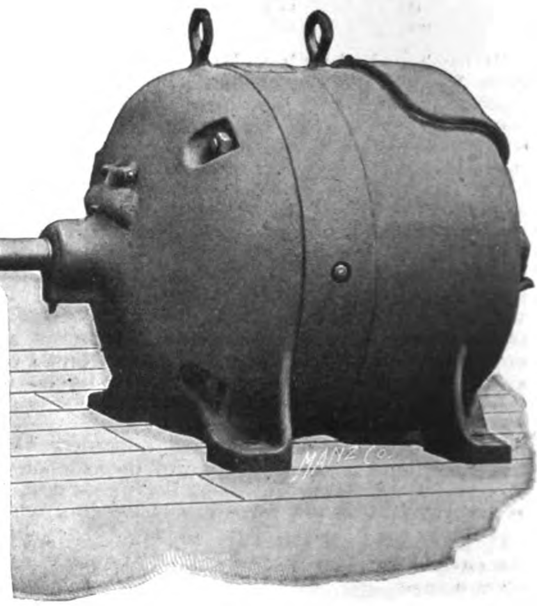
The armature is of the tooth ring form with wire all on the outside. The fields are wound by machinery on forms, being thoroughly insulated and taped before being slipped into the slots which are insulated independently. A two-path winding is generally used, admitting of the use of two brushes, but for heavy currents and low voltage four brushes may be used. The engraving shows the machine equipped with four self-adjusting radial carbon brushes. No provision is made for rotating the rocker arm, as the diameter of commutation does not change materially under changing loads.

The pedestals and bearings are very massive, and have bronze bearings, each of which is oiled by two loose rings dipping into an oil receptacle below. The depth of oil in this receptacle is indicated by the gauges shown.

Each machine is equipped with sliding base, belt tightener, screw ratchet lever, pulley and non-combustible field rheostat. The terminals are mounted on a handsome polished slate slab attached to the lower half of field ring.



EDDY DYNAMO.



ELWELL-PARKER ENCLOSED MOTOR.

EDDY ELECTRIC CO.—The Eddy Type "G" generators consist of a cast iron octagonal frame, to which are bolted four cast steel poles, with flanging tips. Each pole is excited by a field coil, wound on a metal spool, the shunt and series portions in separate compartments. Each layer of wire is insulated from the next by a sheet of tough paper, and the whole winding is thoroughly insulated from the spool by layers of paper, cardboard and mica. Cast with the lower portion of the field frame are extensions for supporting the pillow block bearings. The bearing shells are self-aligning and self-oiling, and well babbitted.

The armature consists of a laminated and ventilated core of sheet iron, mounted on a sleeve which is forced on and keyed to the shaft. The windings are made up of copper rods of rectangular section, embedded in insulated slots in the surface of the core, and spirally shaped copper ribbons connecting them on the ends of the armature.

The commutator is made up of segments of hard copper beveled on the ends and held in place by collars bolted together. The bolt nuts are secured by an efficient nut lock which simultaneously binds all the nuts. Either tangential or radial holders are supplied with these machines. In either form the brush is held against the commutator by a pressure regulated at the will of the attendant, and in such a way as to prevent rattling and jumping.

ELWELL-PARKER ELECTRIC CO.—The illustration shows this company's enclosed motor which was fully described in our last issue, together with the company's semi-enclosed type of machine.

FISHER ELECTRICAL MANUFACTURING CO.—This company's machine has a magnetic frame of cast steel, the shunt and series coils being wound separately and secured to the pole pieces by suitable clamps.

The slotted type of armature is used in this machine. The coils are so designed and placed in the armature that they are interchangeable at every point. They are of equal length and ample conducting capacity.

These machines are built in sizes from 1 to 60 kilowatts.

EXCELSIOR ELECTRIC CO.—This company's "Churchward" six-pole belt-driven generator has its frame cast in one piece, of a special metal, of high permeability. The armature shaft is short and its diameter large, and hung low to insure stability. The armature is designed so as to limit the rise in temperature to 40 degs. Cent. The magnetic proportions of armature and fields are such that sparking is prevented under all conditions of load. The bearings are self-oiling and aligning, and by taking out two bolts the machine can be taken apart in a few minutes.

The following table gives data regarding the Churchward slow-speed belt-driven machines.

The Churchward generators are also constructed for direct driving.

FORT WAYNE ELECTRIC CORP.—This company's Wood direct current generator is shown in the accompanying engraving. It represents their 50-kilowatt 6-pole machine running at 275 r. p. m.

GENERAL ELECTRIC CO.—The slow and moderate speed belt-driven generators of the General Electric Co. embody the latest improvements in dynamo design, and possess all the valuable features of the older form of this same machine, such as cast steel pole pieces, ventilated armature core, machine wound coils on the armature, carbon brushes, tough and moisture proof insulation, etc.

The four-pole construction is used in the larger sizes down to and including the 6.5 kilowatt slow speed, and the 9 kilowatt moderate speed. The general appearance of the machine is well illustrated in the accompanying engraving. For the smaller sizes the two-pole construction is adopted as is indicated by the symbols I. B. (iron-clad, bipolar), by which these machines are designated. This machine is also illustrated, showing its compactness and general neat appearance.

Below we give a table of the company's new slow speed and moderate speed belt-driven generators.

INTERIOR CONDUIT AND INSULATION CO.—The Lundell motors and dynamos manufactured by this company are encased in a steel shell, so that field and armature windings are thoroughly protected. A single coil energizes the fields and the armature is iron clad, no wires being exposed on the surface. Both dynamos and motors of this company are designed for slow speed and direct connection. The illustration shows a four-pole type of machine. Below is a table of sizes and capacities.

TABLE OF LUNDELL MOTORS AND DYNAMOS.

* 4-pole type; all smaller sizes, 2 pole type.

NORTHERN ELECTRICAL MANUFACTURING CO.—This company's specialty is direct connection of slow speed, direct current motors to all kinds of machinery. Their motors are built entirely of soft steel with machine made coil wound armatures and drop forged commutator bars. All their standard motors may be run inverted hung to the ceiling, or half inverted bolted to the side wall and will operate in this position as well as though resting upon the floor. Another feature of the machine is the self-locking sliding base, which, when belted connection is used, is a very handy arrangement. The illustration shows a 1 horse-power motor equipped with pinion for gear connection to press.

KEYSTONE ELECTRIC CO.—The base of this company's machine having combined with it the journals, is strongly constructed of cast iron, but so designed that no unnecessary amount of metal is used; thereby reducing the floor space occupied by the machine and effecting a saving in transportation charges.

The field yoke or ring, cast in two parts, is made of open hearth steel of the highest magnetic permeability, and is consequently very light for the output of the machine. The poles, also of open hearth steel, are bolted to the yoke. The spools, on which the field coils are wound, are placed on the poles before the latter are bolted to the field yoke, thereby making the coils readily accessible by simply removing the cap screws that hold the poles in place.

The armature is of the well known iron clad type, wound with coils placed in slots and completely embedded below the surface of the core. The core, built up of well annealed sheet

iron discs, separated at intervals by brass ventilators, is mounted on a cast iron spider, made in two parts, and bolted together after the core has been brought to its proper length by hydraulic pressure.

The change-of-plane-rings, cast on the spider, with openings between them and the flanges, provide means for ventilation; air being drawn from under the ring at the pulley end of the machine, it is forced out between the coils at ends of armature as well as through the openings in the core.

As will be seen from the tables of sizes herewith, all machines have been designed to give their full rated capacities at 110, 220 or 500 volts, the generators being over-compounded 5 per cent. standard, but are wound for any other percentage up to 10.

RIDGWAY DYNAMO AND ENGINE CO.—The Thompson-Ryan dynamo, manufactured by this company, represents a radical departure from the general design of continuous current generators on the market. Its chief distinguishing feature is a bushing ring surrounding the armature and forming part of the magnetic circuit, and carrying coils connected in series with the armature. The chief office of these coils is to neutralize the distorting effects of armature reaction, and to produce an independent commutation field of variable strength, and exactly sufficient for the proper reversal of the current in the armature coils as they pass the brushes. The result is the securing of perfect commutation, even under the most extreme variations of load, and with brushes absolutely fixed in position. The fixed losses of these generators are extremely low, giving very high efficiency under light loads. The chief claim for them is their high efficiency and remarkably perfect operation under the most extreme variations of load.

We append a table of sizes, of both belted and direct connected generators, the manufacturers making a specialty of the latter, as they build both engines and generators.

TABLE OF THOMPSON-RYAN GENERATORS.

200	500	10,500	200	180	14,200

RIKER ELECTRIC MOTOR CO.—The machine shown in the accompanying illustration is of cast steel with toothed armatures.

The armature cores of the smaller sizes are keyed to their shafts and the armature cores of the larger sizes are keyed to a spider secured to the shaft. The construction of this spider facilitates radiation and insures a cool running armature and machine. On all multipolar sizes former wound armature coils are used—giving an electrically and mechanically balanced armature. The field coils are wound upon thimbles with brass ends and are insulated with mica.

The brushes which are of carbon are held in position by a brush holder which feeds the brush automatically and always in the same line. The machines are so designed that the brushes do not require shifting from no load to full load.

The bearings are fitted with phosphor bronze bushings and oil rings. The latter dip into an oil well in each bearing pedestal and efficiently lubricate the shaft. The efficiency runs from 75 per cent. on the small bipolars to 95 per cent. on the larger multipolar machines.

The following table gives the capacity, sizes, etc., of the Riker machines:

TABLE OF RIKER DYNAMOS AND MOTORS.

Kilowatt.	Type.	R. P. M.	Inches Floor Space.
⅛	Bipolar.	1,900	9¾x6¾ in.
¼	"	1,800	12⅛x7½ "
½	"	1,700	15⅛x10 "

THRESHER ELEC. CO.—The illustration shows the iron clad type B machine manufactured by this concern, in sizes from 1 to 30 kilowatts. Its principal features are its strength, simplicity and compactness, all the parts being interchangeable. Owing to its iron clad construction, it is of very high efficiency, the magnetic material being so placed as to correspond with the theoretical lines of magnetic force, thus reducing the leakage to a minimum. It is free from vibration, the center of gravity being very low, and the openings are so arranged that all parts are easily accessible and perfect ventilation is afforded. The bearings are self-oiling and self-centering and universally supported. The armature is exactly balanced and wound in such a manner that the coils of highest potential are farthest apart. One particularly noticeable feature is that the armature and field coils are entirely protected from moisture, dirt or abrasion. The speed is slow and the regulation perfectly automatic. These features are pointed out as making the machine especially desirable in isolated plants, where, as a rule, dynamos and motors receive very little care. Below are given capacity, speed, weights, etc., of the different sizes of these machines.

The company also manufacture belted multipolar machines (see illustration), from 30 to 150-kilowatt capacity and direct connected machines from 4½ to 150-kilowatt capacity. The latter are of the same general style as the belted machines, but run at a much lower speed, the 150-kilowatt machine, for example, running at 225 r. p. m.:

K. W.	Speed. inch.	Height. inch.	Length. inch.	Width. inch.	Weight. Pounds.
2	1600	19¾	29	21⅞	530
4	1475	23⅛	33½	21⅞	864
6	1275	27⅝	41	24¾	1225
9	1250	27⅝	41	24¾	1500
12	1050	30⅝	42⅜	23¾	2000
15	950	36⅝	49	33	3255
18	900	37⅝	49	33	3950
24	825	40⅞	54⅝	38¾	4660
30	775	42⅛	56⅝	38¾	5030

WALKER COMPANY.—The engraving gives a general view of the standard direct-connected Walker generator. The sparkless running of the Walker machine is secured by a number of ingenious points of design. First, that of the brush holder; the brushes have a most liberal contact in proportion to the amount of current they are required to carry and the commutator bars are sufficiently long to permit of enough brushes being placed upon them for the ready accomplishment of this requisite. The armature winding is exactly symmetrical and there is but one coil of wire per commutator bar. This greatly diminishes the self-induction of the commutator coil and practically eliminates the sparking due thereto.

The field poles are wound with absolute accuracy even to the fraction of a turn and as all of the coils are in series the magnetizing power of each is the same, thus preventing the sparking of individual sets of brushes. Lastly the field is so strong that it completely quells the armature reaction, but so well designed is its magnetic circuit that only a small percentage of magnetizing current is necessary. Prompt and accurate regulation is secured first by having an armature of extremely low resistance so that the range of magnetization in the field necessary to produce the appropriate change of voltage of the armature is very small; and, second, the use of laminated iron pole pieces which by their freedom from eddy currents allow any change in the magnetizing current to almost instantly establish itself. The field frame of the machine is of cast iron. The combined losses of the machine at full load are stated to be less than 5 per cent., thus giving an efficiency of 95 per cent. at full load.

WESTERN ELECTRIC CO.—The general type of this company's belt driven machines is shown in the accompanying engraving, the lower half of frame, the sub-base, and bearing pedestals for the 4-pole type being made in one casting, with the exception of the 17-kilowatt, which has a separate subbase. For all sizes less than 17-kilowatt capacity, the whole frame, including pole pieces, is made a part of one casting with the sub-base and bearing pedestals.

The armatures are of the iron-clad type, having copper bar conductors imbedded below the surface in insulating tubes, and, for the larger sized machines, are connected at the ends by spiral end connectors, there being no band wires used. The insulating tubes are made up of alternate layers of press board, oil paper, and mica, and are made to completely surround the conductor.

Special attention is given to the point of proper ventilation of the armature so as to prevent the accumulation of heat in any part as well as to prevent the general heating.

The field coils are machine wound on brass spools, making them interchangeable. The wire is insulated from the spools with press board and mica. The coils are thoroughly ventilated and are so mounted on pole pieces as to be perfectly insulated from the pole pieces and dynamo frame.

All brushes are of carbon and are so arranged in their respective holders that each one may be removed or adjusted independently while the dynamo is in operation, or all may be moved simultaneously about the commutator. The brush holders are so constructed as to force the brushes in the direction of rotation of the armature, thereby doing away with chattering. The brushes are clamped rigidly by their holders so that the current passes through clamped joints only and does not depend on any sliding contacts for a conductor. At the same time each brush is perfectly free to move, and is given tension on the commutator by a phosphor bronze spring. The tension spring is not depended upon for carrying current; therefore there is no possibility of its becoming heated and losing its elasticity.

These machines are built in sizes from ½ kilowatt to 250 kilowatts, the larger sizes having six and eight poles, depending upon the speed at which they are to be run.

The company's direct-driven dynamo follows the constructive details of the belt-driven machines quite closely. It is built in capacities from 5 to 500 kilowatts and from 120 to 550 volts.

V. ALTERNATING GENERATORS.

ALTHOUGH a later arrival on the scene of heavy electrical engineering work, the alternator has more than held its own alongside of its older brother. The efficiency of alternators, at first somewhat inferior to that of the direct current machine, is now fully abreast of it. In addition to the single phase the two and three-phase generators have been reduced to standards and not a little of the work of the future may be expected to be done with these types.

IDEAL ELEC. CO.—The toothed armature of this company's La Roche alternator is built up of the best quality of Norway iron, well laminated and ventilated, the plates being separated by a specially prepared paper. The coils, which are well taped and insulated from the core with mica, are easily put in place and removed, as required, and are entirely below the surface of the armature where they cannot possible be injured. The ends of the coils are furthermore protected by an ornamental brass shield, which, besides giving the armature a handsome appearance, improves the ventilation. The coils are so connected that the e. m. f. between adjacent coils is reduced to a minimum.

The fields are of the separable ring type and the field magnets are readily detachable, being held in place by an improved locking device. The bearings are of the self-aligning and self-lubricating type, and are of large size to ensure cool and smooth running.

The Ideal Electric Co. also manufacture multiphase machines as well as machines of any frequency. These machines are either simple shunt, compound wound, or entirely self-exciting, as may be desired. This company also build a small line of alternators and has recently made a specialty of alternators for college and scientific uses. The commercial machines range in size from 2 kilowatts to 500 kilowatts. The machines used for laboratory, school and scientific purposes, range from 2 to 10 kilowatts.

FORT WAYNE ELECTRIC CORP.—This company's Wood alternator connected with exciter is shown in the engraving on this page. It represents their low frequency machine of 150 kilowatts, wound for 1,000 or 2,000 volts, and running at 450 r. p. m.

GENERAL ELECTRIC CO.—The accompanying illustration shows this company's 32-pole, 250-kilowatt monocyclic generator running at speed of 470 r. p. m. and serves to illustrate the general construction of the smaller sizes of this type.

NATIONAL ELECTRIC CO.—This company's new line of alternators are designed for a frequency of 125 periods per second, and operate at speeds from 1,500 r. p. m., for the smallest size, which is of 500 lights capacity, to 1,050 r. p. m. for the 2,500-light size. These machines are constructed with laminated steel pole pieces cast in the field ring. The armature is of the iron clad toothed type with removable coils. The coils are machine wound in standard forms and are finished up complete and tested before being applied to the armature core. The armature core is built up in the usual manner of thin sheet steel discs supported on a hollow spider. The discs are punched with slots of a particular shape which line up longitudinally when the discs are assembled and form recesses in the core for receiving the armature coils. The armature core is divided into sections perpendicular to the axis of the shaft, distance pieces being provided to preserve fixed distances between the sections. These spaces between the sections of the core serve the two-fold purpose of receiving the metal links which hold the coils and of providing air channels for ventilation.

The coils are easily slipped in place on the core without driving, bending or wedging. They are held in place by means of aluminum-bronze links, or retaining pieces, which have the shape of an inverted U. At the end of the armature finish rings are attached for the purpose of covering and holding down the ends of the coils and to give the whole a neat appearance.

These generators are provided with multipolar iron clad direct,connected exciters attached to the main dynamo frame. The alternators are compounded so as to maintain a constant potential or to develop any desired percentage of increase in voltage proportionately with the load.

THE ROYAL ELECTRIC CO.'S alternator is an inductor dynamo. The dynamo is provided with a single field magnet core, closely surrounded by a single exciting coil. In its complete state the exciting coil is invisible, being covered by the projecting pole pieces of the field magnet, which embrace the armature blocks on which two sets of armature coils are mounted.

The machines are built in sizes of 500, 650, 750, 1,000, 1,250, 1,500 and 2,000 lights. The standard pressures are 1,000 or 2,000 volts. They are adapted to be connected from 100 to 2,000 volts, but the lower pressures require special connections.

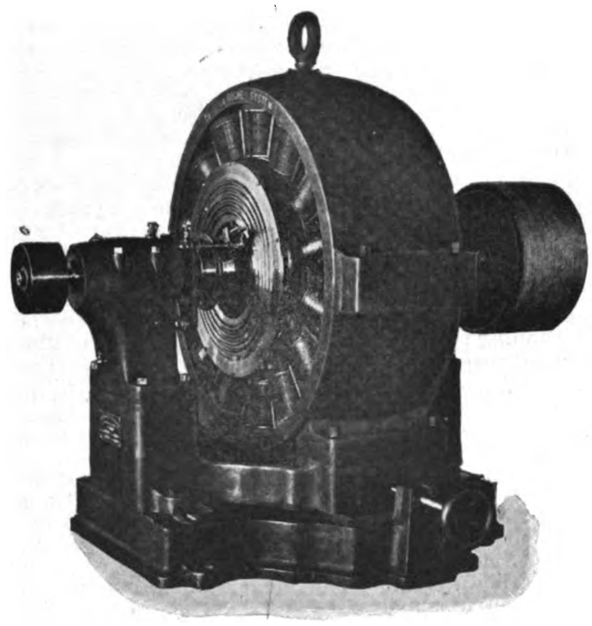
The table below gives the approximate floor space, weight and speed of the dynamos:

Capacity in 16-c.-p. lights.	Speed. R. P. M.	Floor Space in inches.	Approx. wt. in pounds.
500	1100	41 x 62	3000
650	1100	41 x 67	3400
750	1100	45 x 72	4000
1000	950	48 x 80	6000
1250	860	48 x 86	7200
1500	860	56 x 92	8500
2000	800	56 x 98	10000

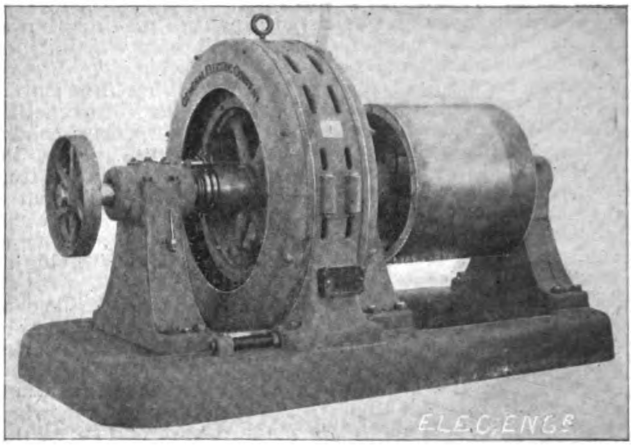
The smaller machines have an efficiency of 93 per cent. at full load, and the larger ones 95 per cent. Owing to the more than ample cross section of conductors as compared to the current they carry, the heating is below that required in the most stringent of specifications. The magnetic density is kept very low.

This special type of machine has a particular wave form factor, which reduces the transformer core losses.

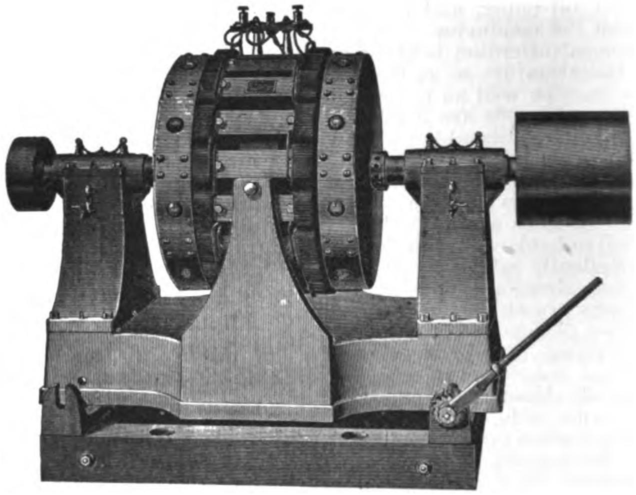
STANLEY ELECTRIC MANUFACTURING CO.—The S. K. C. generators of this company are built for operation either as two phase or three phase machines and by slight modification can be designed for operation as single phase machines. The generator has no moving wire and consequently no collector rings, commutators or brushes. In gaining these points nothing is sacrificed in electrical properties. The armature is stationary and split vertically so that either half of the armature



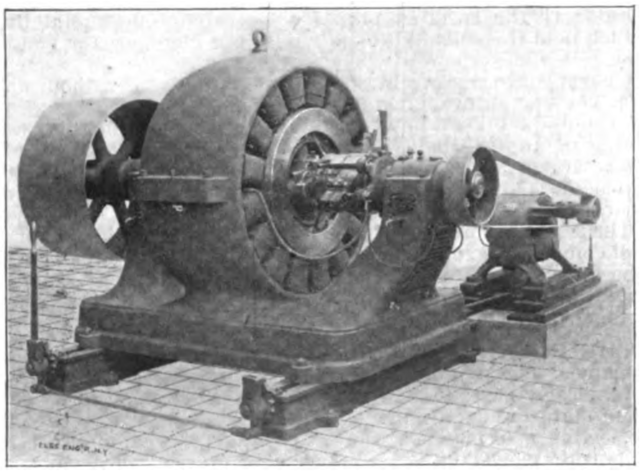
La Roche Alternator.



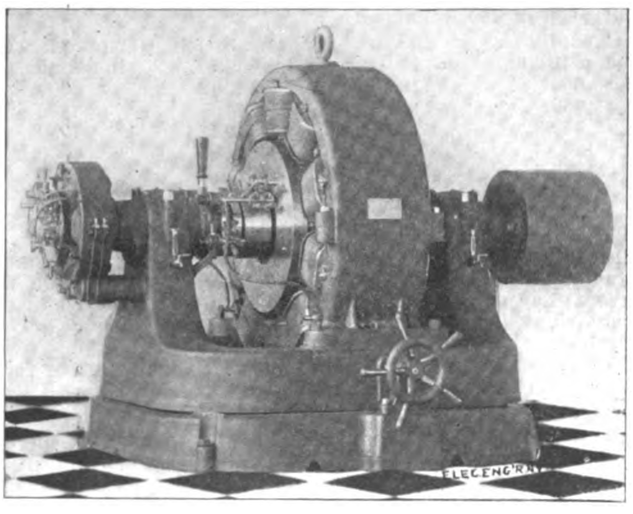
General Electric Monocyclic Alternator.



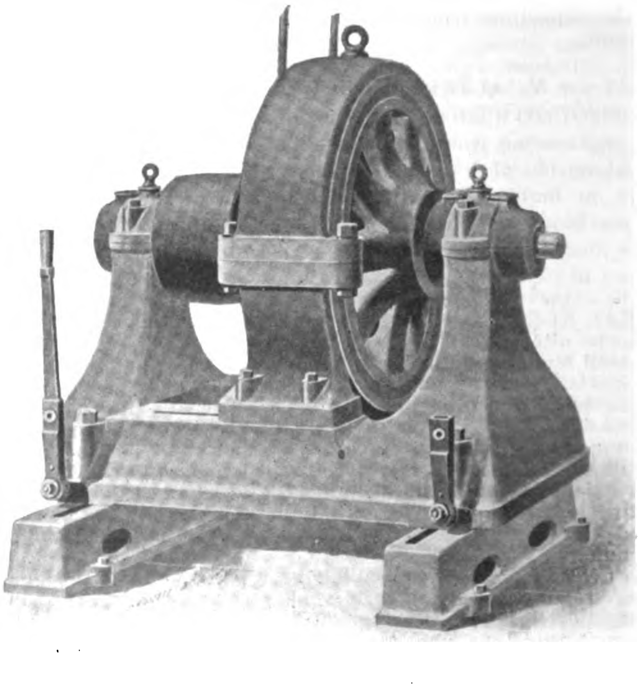
Royal Electric Co. Alternator.



Fort Wayne-Wood Alternator.



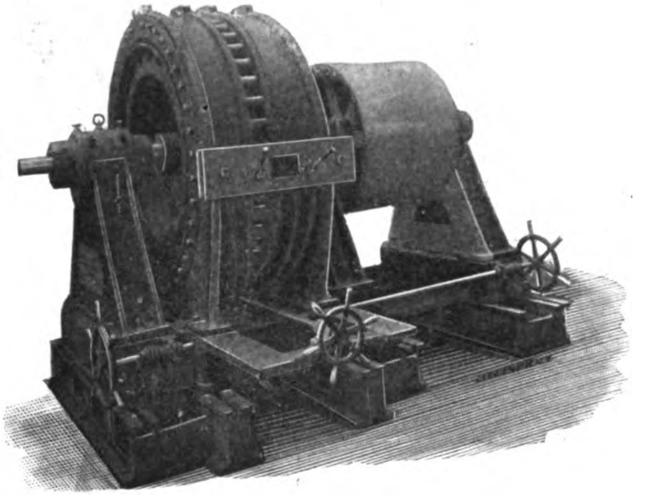
National Electric Co. Alternator.



Walker Inductor Alternator.

can be drawn back a sufficient distance to allow access to the coils. The field coil is stationary and is supported by the armature frame. The revolving part, or inductor, corresponds to what might be called the core of the field in the older types of alternating current generators. Proper devices are attached to the machine for drawing back the two halves of the armature and for shifting the machine as a whole upon its bed frame. The bearings are self-aligning and of the self-oiling ring type.

All wires from the generator are brought to a marble terminal board attached to the side of the generator. On this marble board are provided terminals for connection with the line or switchboard and also two regulator heads by means of which the effective length of armature wire of each phase can be increased or diminished through considerable latitude, thus allowing each phase to be regulated independently. The inherent regulation of these generators is very close and the efficiency high. The generator is exceedingly simple, the bearings being the only part of the machine subject in any way to wear.



S. K. C. Inductor Alternator.

WALKER ALTERNATOR.—This machine is of the inductor type and having been described in detail in a recent issue of the Engineer, an exhaustive description is not necessary. The machine has no moving wire, the rotor consisting of a pair of discs with projecting iron spokes, the ends of which are laminated. A single field coil serves to excite them and they distribute their magnetization to the coils of the armature, which is also stationary. The armature teeth are so arranged that it is a matter of but an hour's work to remove all the coils and replace them with either a two or three phase winding and any system of connection can be easily obtained. Like the direct current generators, the stationary portion of the Walker generator can be slid sidewise over the pulley, thus exposing all of its windings to ready inspection or repair.

WESTINGHOUSE ELECTRIC AND MANUFACTURING Co.—The company's two-phase generator of 75 kilowatt capacity, runs at 300 r. p. m. This particular machine delivers current at a potential of 440 volts and a frequency of 60 cycles per second, or 7,200 alternations per minute.

III.—ARC DYNAMOS.

THE most marked improvement which the standard arc machines of to-day exhibit is their excellent regulating qualities and their high insulation. It is this latter fact that has made it possible to construct machines operating 150 full arc lights of 2,000 candle power nominal, and machines of still greater capacity are in course of cosntruction, a 300-lighter being actually on the tapis.

BRUSH ELECTRIC CO.—While the general type of the dynamo is the same as the early dynamos, yet great improvements have been made, and they are modern in all respects. Their efficiency is at least 15 per cent. above the original machines. The mechanical features have received special attention. The dynamos can be very quickly and easily taken apart, so that the removal of an armature, field magnets and other parts of the machine is a matter of a few moments. Any one armature coil can be repaired without disturbing any of the others. The regulator attached to the machine itself, is belted to the shaft. Magnetic clutches control the shifting of the brushes and at the same time throw resistances into and out of the circuit as needed. The wall controller in connection with the regulator ensures perfect regulation of the current.

The 80, 100 and 125 lighters have been the most popular of these machines. Others of much larger capacity are being designed. When these are completed, the Brush Company will have about eight modern improved Brush arc dynamos, each of a different capacity, and ranging from 50 lights up to 300 lights.

The question of high potential is an exceedingly interesting and important one in connection with these large arc dynamos. The demand for large dynamos and the objection to very high potential on the lines, led to the necessity of some method permitting of the former, and solving the latter problem. Mr. C. M. Green, one of the electrical engineers of the Brush Company, solved the problem by designing what is now known as the Brush multi-circuit arc dynamo. The circuit of the dynamo may be divided into two or more separate circuits. The greatest potential around the interior circuit of the dynamo and the exterior or lamp circuit will be that of the greater circuit. The arc lamps may be divided equally on two or more circuits, or they may be divided with any number of lamps on any one circuit, provided the total number of lamps does not exceed the total capacity of the machine.

The most popular of these multi-circuit dynamos have been those with two circuits of 62 lights (about 3,100 volts) each, on the dynamos of 125 lights capacity. These have been used largely for central stations. In isolated plants, the 125-arc light dynamos, divided into three circuits of 42 lights or about 2,000 volts, have been the most popular.

The advantages of these large arc dynamos with the multi-circuit arrangement are numerous. They effect saving in floor space, engines, cost of attendance, oil, belts, flexibility in the handling of circuits, use of large units with corresponding increase in efficiency and reduction of high voltages on the circuits.

EXCELSIOR ELEC. CO.—This company's arc light generator consists of two field cores connected by a cast-iron yoke at one end, and provided with pole pieces at the other, which encircle the armature on three sides. The armature is so placed that its shaft rests in bearings which are on the interior of the machine, so that the armature can be entirely exposed. This is facilitated by the pole pieces, which are hinged, and which can be turned out so as to expose the armature completely, and allow it to be drawn out a sufficient distance for thorough repair, if necessary, without removing the shaft from the journal bearings.

The regulation is effected by shifting the brushes in conjunction with a regulating resistance, both of which are simultaneously operated by a small auxiliary motor. This motor, which is entirely hidden from view, is situated in the hub-like projection bearing on the arms which span the two pole pieces beside the end of the armature shaft, and which might be mistaken, except on closer scrutiny, for the bearing of the shaft. This small motor is fixed in a magnetic field, which is produced by attaching the cast iron arms shown to each pole piece and bringing them together so as to surround the armature of the small motor.

The machines are built in sizes from 15 lights up to 150 of 2,000 candle power, taking 9.6 amperes, and up to 200 lights, 1,200 candle power on 6.8 amperes.

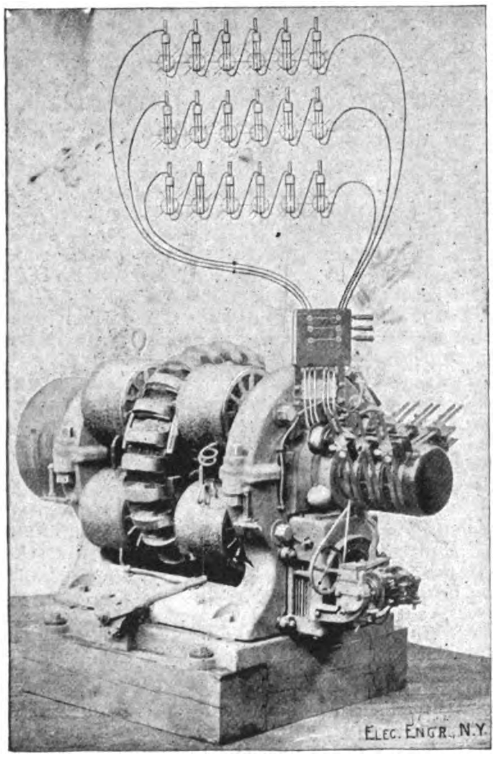
WALKER ARC MACHINE.—The Walker Co. are in possession of a number of patents on arc lighting and an arc machine is in progress of construction. It is expected to construct larger units in its arc lighting than have heretofore been supposed to be possible.

WESTERN ELEC. CO.—This company's arc machine is of the bipolar, horseshoe type, with the magnets horizontal. The magnet cores are made of wrought iron and the pole pieces and yokes of cast iron. The bearings are of the self-oiling and self-aligning type, being provided with visual oil gauge and drain.

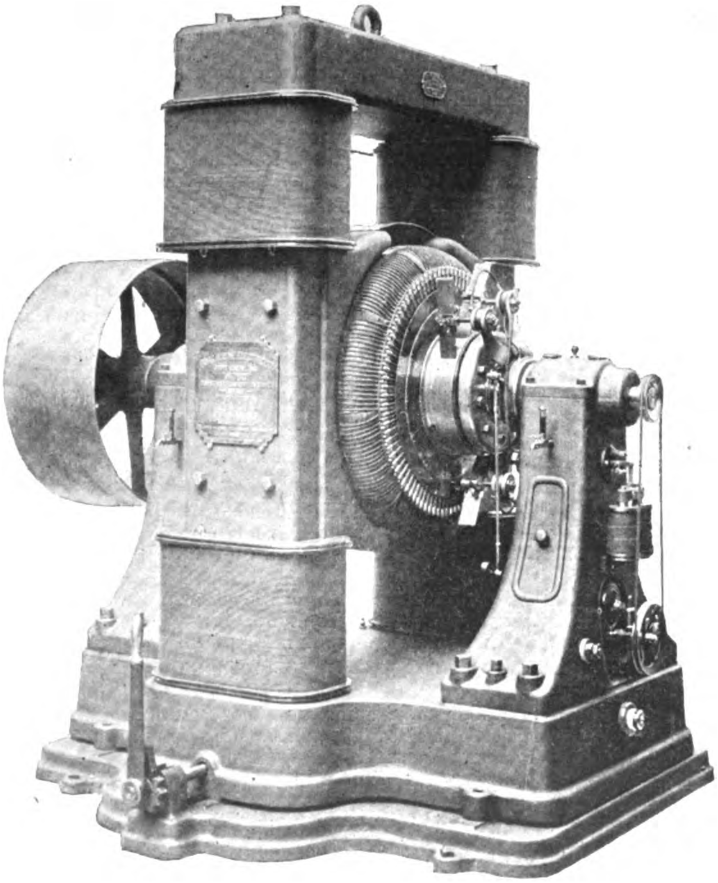
With the construction adopted, the removal of the armature for examination or repairs is a very simple matter. The bearing may be removed in about five minutes, the pulley in three, and the commutator in ten. The average time taken for one man and helper to wind an armature coil for an 80-light machine is fifty minutes, this armature being of average size.

The armature is of the iron clad type and particular attention has been paid to the insulation and ventilation.

On the yoke of the machine shown is mounted a pair of reducing switches which cut out part of the field winding. The lower switch is for the purpose of adjustment so that there is very little liability of flashing the machine when it is operating under extremely variable loads. The other switch is for the purpose of reducing the current output of the dynamo so that if it is desired to run the machint part of the time at a lower current than its normal amperage, this switch can be closed and the regulator adjusted to the lower current. In this way considerable fuel can be saved when it is not necessary to run the lights at full brilliancy.

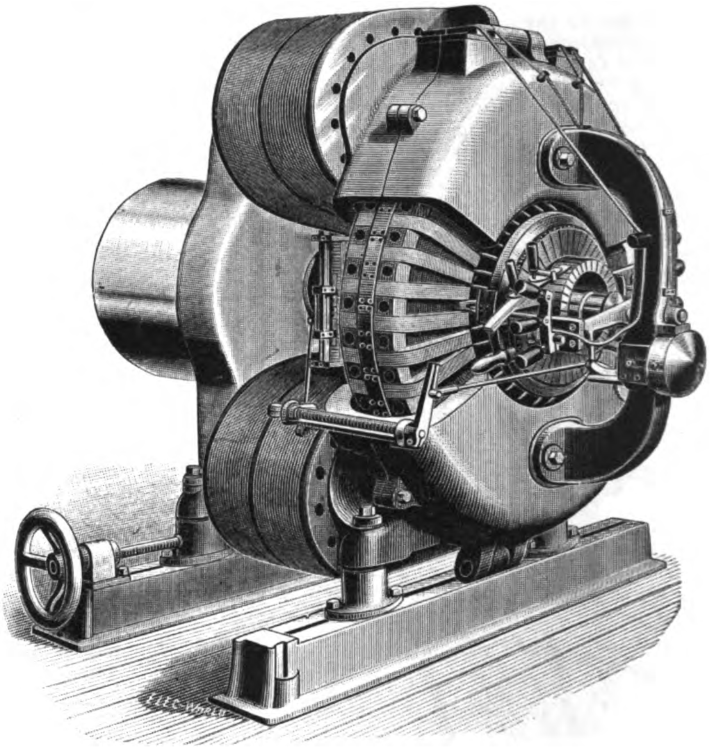


BRUSH ARC DYNAMO.

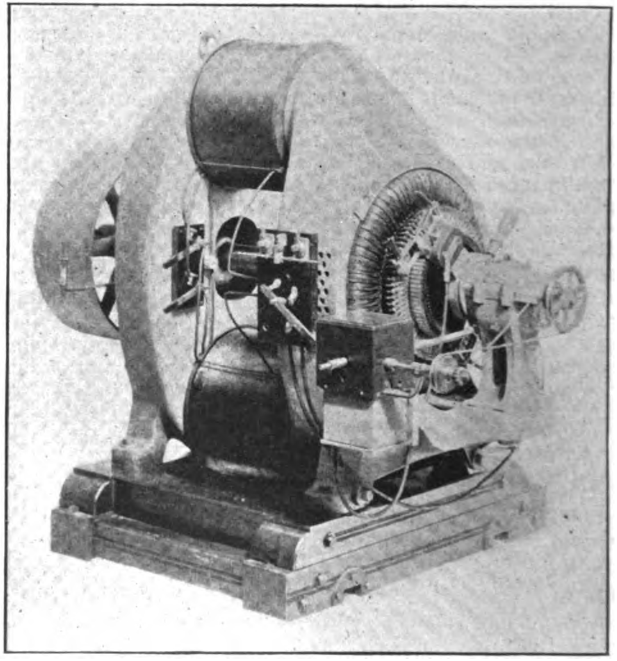


FORT WAYNE ARC DYNAMO.

WESTINGHOUSE ELECTRIC AND MANUFACTURING CO.—The company's 75-light direct current series arc machine is of the open coil type, delivering a unidirectional though not an absolutely continuous current. It is claimed that the open coil dynamo, with its pulsating orm of current, is particularly well adapted for arc lighting, as the pulsating effect, while giving a steady mean value to the current, causes a very slight but constant vibration in the mechanism of the lamps, thereby reducing the chance of sticking, or failure to feed, to the minimum. The company have introduced a decided novelty here, however, by using a two-phase armature, the current of course being commutated. The resulting direct current seems to adapt itself practically to all forms of series arc lamps in use.



EXCELSIOR ARC DYNAMO.



WESTERN ELECTRIC ARC DYNAMO.

The armature is made of high grade laminated steel sheets, punched with "T" shaped teeth at the periphery. The armature coils are wound on molds with great care, are very thoroughly insulated and tested independently; afterwards being mounted on the armature teeth, where they are held in place by wooden wedges, dove-tailed in. This is the same form of armature that is employed by the company in their alternating current incandescent generators. There is no wire on the outside of the armature, which can be handled, or even rolled upon the floor, without fear of damage to the winding. The commutator segments have seldom to be renewed, but are readily replaceable when worn out. By the use of the two-phase current above referred to it has been possible to produce a direct current on the open coil form of dynamo which does not yield vicious sparking at the commutator.

This machine regulates its current with great nicety, simply by the reaction between the armature and the field, without the introduction of any wall regulating devices whatever. Once adjusted for a given current, the dynamo will maintain this current under considerable fluctuations of speed and wide changes of load. In addition to this fact, should it be desired to reduce the current to any point below its normal amount, this can be done by an adjustment of the field current, and the dynamo will maintain the same close regulation at the reduced current as at its normal current.

A small direct current machine furnishing a 100-volt current is employed to excite the fields, which are therefore free from chances of grounds.

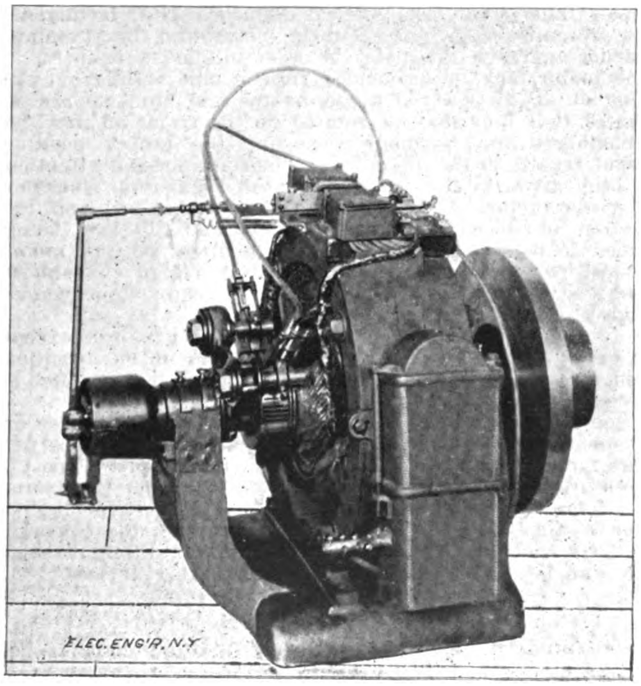
These machines are built in capacities from 40 to 75 lights.

FORT WAYNE ELECTRIC CORP.—This company's Wood arc generator has reached a high state of development. Its automatic regulator, in connection with the variable double-brush contact, effect a remarkable regulation of current even under the greatest fluctuations.

ALTERNATING MOTORS.

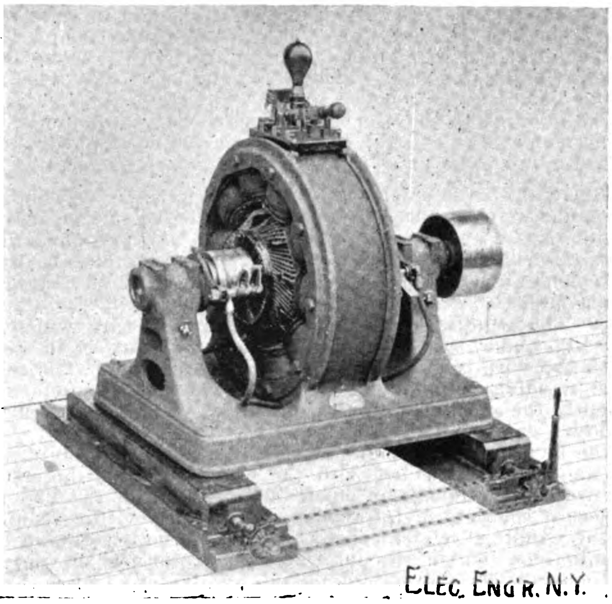
THOUGH the number of types of alternating motors is small, they present an interesting exhibit of the methods employed for solving one of the most difficult problems that has ever been presented to the electrical engineer. It may fairly be claimed that the main difficulties have been conquered, though the straight out-and-out, non-synchronous single-phase alternating motor has still to make its appearance.

EXCELSIOR ELECTRIC CO.—This company's new Churchward motor is a single-phase machine. It is provided with an automatic synchronizing switch and operates on 25 to 150 cycles per minute.



Excelsior Electric Churchward Single-Phase Alternating Motor.

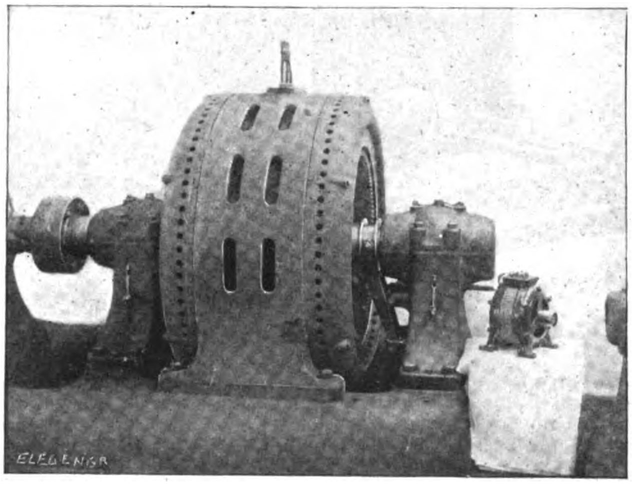
FORT WAYNE ELECTRIC CORP.—The armature of this motor is of the ring type, and carries two windings, one a distributed winding, wound in the teeth on the periphery and connected to a commutator which is placed on one end of the shaft; the other winding is a concentrated one, having as many coils as there are field poles, and connected to two collectors at the other end of the shaft. The fields are laminated. The machine runs as a simple continuous current series motor at the start, and hence with full torque. When synchronism is reached, the switch at the top is thrown and the machine then operates as a synchronous single-phase motor.



Fort Wayne Single-Phase Alternating Motor.

GENERAL ELECTRIC CO.—The General Electric Company now manufacture a complete line of three-phase and single-phase induction motors for 60 cycle and 125 cycle circuits. The three-phase motors can also be wound as two-phase machines, with only minor changes.

In all of these motors the construction is simple and substantial. Both the armature and the stationary field are of the iron-clad type, wound with machine-formed interchangeable coils. The field windings are covered at their ends by shields which protect them from dirt and mechanical injury. Both armature and field cores are thoroughly ventilated to insure cool operation. The bearings are spherical-seated, self-aligning and self-oiling, and the pillow blocks are cast in one with the base.



General Electric 3-Phase Motor.

In all but the smallest sizes, a self-contained starting resistance is used to secure good starting torque with a small amount of current. With this construction there are no moving contacts, a simple device consisting of a movable sleeve and stationary contact points being used for short-circuiting the starting resistance when the motor has reached its speed. In the smaller sizes, where a large starting torque is not required, no starting resistance is used.

The three-phase motors for 60 cycles are made in sizes ranging from 1 to 150 horse-power, the illustration showing a 100 horse-power motor of this type. They are wound for 110, 220 and 550 volts, and the 50 horse-power and larger sizes can also be wound for 1,040 or 2,080 volts.

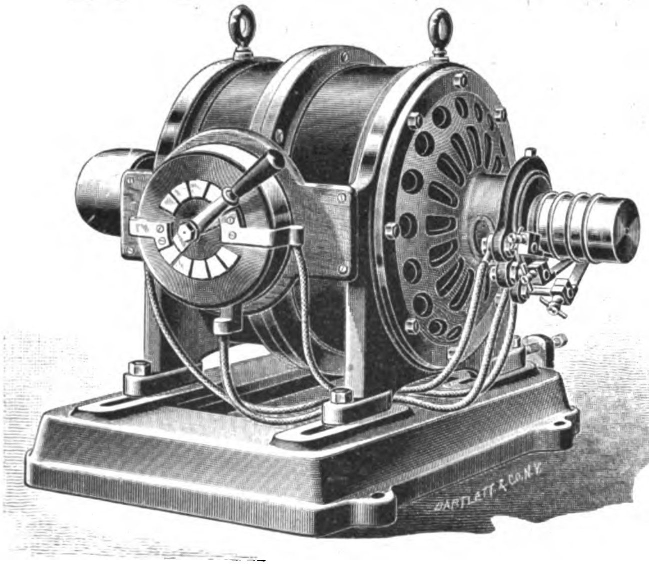
For 125 cycles, three-phase motors are made in sizes ranging from 1 to 20 horse-power, and single-phase from 1 to 15 horse-power, and are wound only for 104 volts. These latter require a starting box which is cut out of circuit when the motor comes up to speed.

The illustration shows a ¼ horse-power special motor of this type, which has been placed beside the 100 horse-power three-phase motor in order to compare their respective sizes.

STANLEY ELECTRIC MANUFACTURING CO.—The S. K. C. motor may be best described as consisting of two parts, a motor proper and a rotating transformer, the two parts alternately exchanging their functions. It consists electrically of two fields, which are fed by currents differing 90 degrees in phase, and two armatures, although mechanically there is but one. The winding is so connected that the wire which lies directly under the field poles on one armature is in series with the wire lying between poles on the other. The armature winding is not connected with the circuit, and consequently the only current flowing in it is an induced current of low e. m. f.

The field coils are wound separately and are the only parts of the motor connected with the circuit. These motors are all wound for operation upon 500 volts e. m. f. The pole pieces of the field of the motor are provided with a "compensating winding," which consists of short-circuited coils of high conductivity which are placed in the motor for the purpose of neutralizing the self-induction of the armature. These motors have a starting torque which varies from 50 per cent. to 200 per cent. greater than the running torque of the motor.

The unique and striking feature of this motor is the use of a condenser, the function of which is to make the motor take a current in proportion to its load, substantially as direct current motors do. The condenser is connected in multiple with the field winding of the motor, and when so placed supplies the lagging component of the current, or, in other words, the false current. The motor is provided with self-oiling bearings, and is substantially built so that when in operation it requires no attention, except to see that the self-oiling bearings are properly supplied with lubricant.

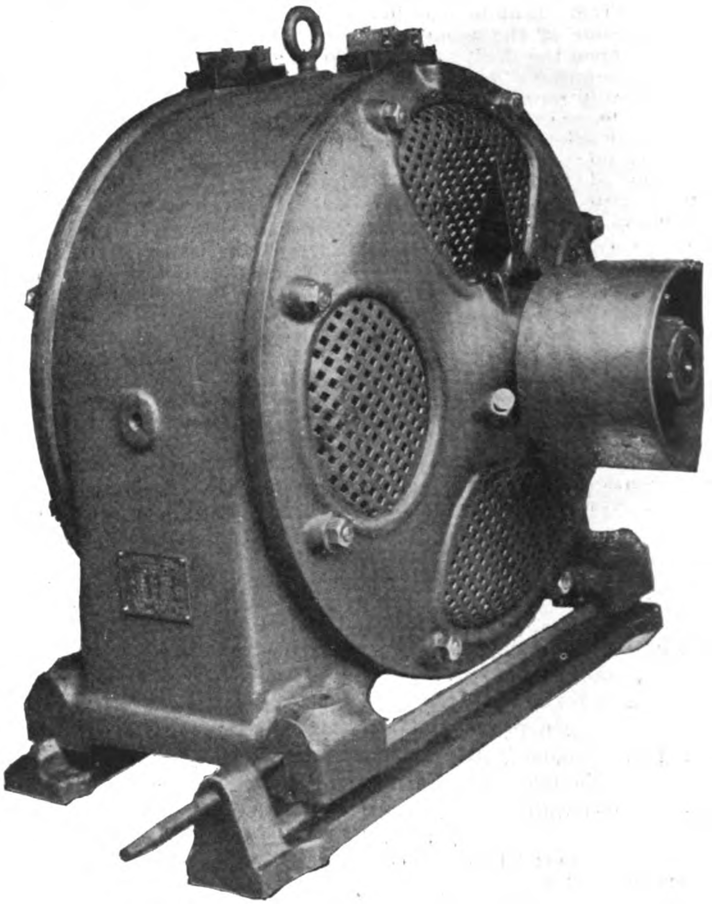


BARTLETT & CO. N.Y.

S. K. C. 2-Phase Alternating Motor.

WESTINGHOUSE ELECTRIC MANUFACTURING COMPANY.—The latest form of Tesla polyphase induction motors manufactured by the Westinghouse Company is illustrated herewith. The machine is reduced to the simplest possible form and consists of a stationary primary, the winding of which is permanently connected to the main circuit by means of the terminals shown on the top of frame, and a revolving secondary, the winding of which is purposely short-circuited, and consequently no accidental short-circuit can possibly cause any damage. The construction is also practically indestructible from heating, raising of coils or mechanical injury in handling.

The housing consists of a cylindrical frame of cast iron in which the primary is mounted and which forms a base for the machine, and also supports the two end brackets carrying the self-oiling bearings. Perforated plates fitted into these brackets both protect the rotating element and permit excellent ventilation. It will be noted that the housing completely encloses the primary and secondary elements, and protects them from any external damage. The starting devices are entirely separate from the motor, and the attendant need not approach the motor in order to start or stop it.



Latest Westinghouse Tesla Alternating Motor.

The motor may be suspended from a side wall, from the ceiling or at any desired angle, as the end brackets are so mounted that they may be rotated on the frame so that the oil chambers may be made to assume the proper position without regard to the angle of suspension. Special attention has been given in the design, to speed regulation, efficiency and power factor. The motor is self-starting at full load, the variation of speed between no load and full load being claimed to be less than that found in direct current motor practice. The efficiency is maintained at a high and almost constant value from full load to one-half load. This secures a high all-day or average efficiency.

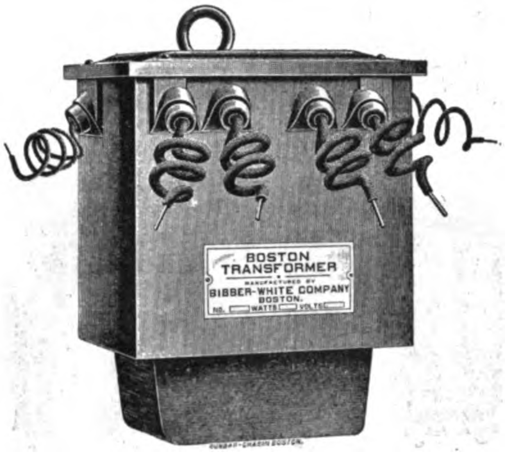
As there are no sliding contacts or friction whatever except that of the journals in the bearings, the amount of attention required is exceedingly small and the cost of maintenance is reduced to a minimum.

"Type C" constant speed motors are built for two-phase or three-phase circuits, for 7,200, 3,600 or 3,000 alternations per minute; and in capacities from 1 horse-power up. "Type C" motors are also designed for a variable speed, for the operation of cranes, elevators, hoists, etc. The variable speed motor is almost identical in construction with the constant speed type, but is especially designed to give a different speed curve and is supplied with suitable regulating devices.

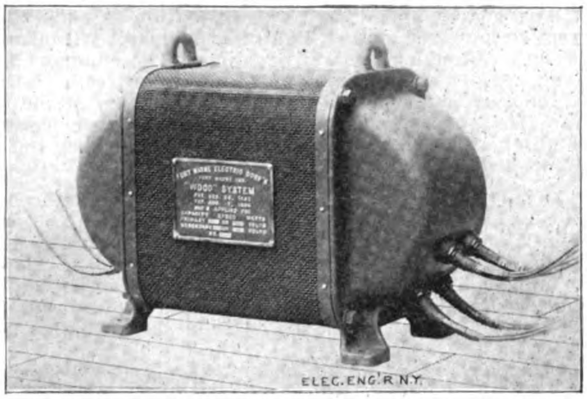
V.—TRANSFORMERS.

THE standard transformer of to-day may lay claim to being among the most efficient apparatus for converting energy in existence, albeit the conversion in the present case involves only a change in potential. The efforts of manufacturers have been largely concentrated on securing the highest possible all-day efficiency, rather than a maximum full-load efficiency. Soft steel properly "aged" has become to be the recognized material of construction of the core.

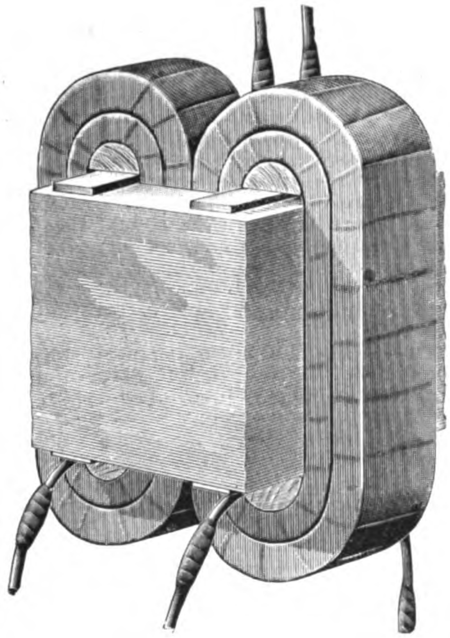
BIBBER-WHITE CO.—In this company's "Boston" trans-



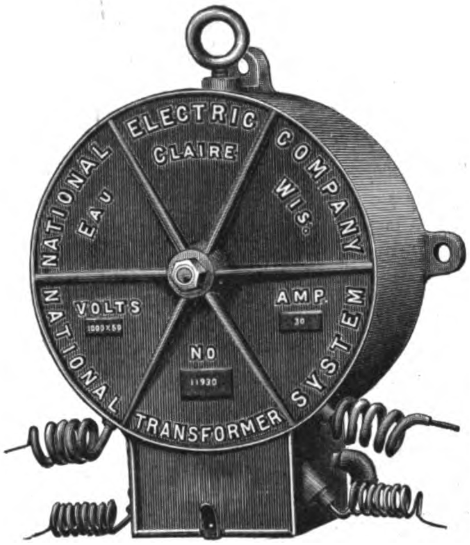
THE "BOSTON" TRANSFORMER.



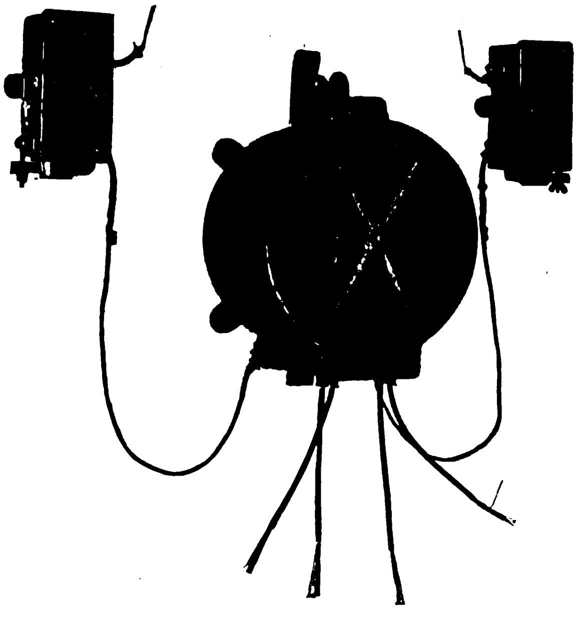
FORT WAYNE TRANSFORMER.



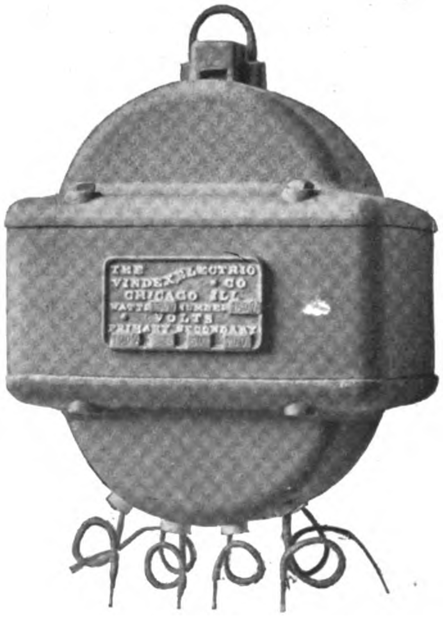
DIAMOND TRANSFORMER.



NATIONAL ELECTRIC CO. TRANSFORMER.



PACKARD TRANSFORMER



VINDEX TRANSFORMER.

former high efficiency and close regulation have been the features particularly aimed at. The insulation is such that a two year's guarantee against lightning is given. All terminals are brought through porcelain bushings. The company advocate the complete separation of transformer from the fuse box. Each transformer is furnished with two single pole, separate fuse boxes, made with removable fuse contacts, which automatically switch off the main circuit when the fuse box is opened.

DIAMOND ELECTRIC CO.—The Scheffer transformer is of the core type, and the coils are divided, making the points of potential far apart, and the danger of current cutting across less than when one coil is used. The ventilation in this type is also enhanced, the copper being thoroughly ventilated. This type is also claimed to be lighter for the same out-put than that of the shell type. Below is a table of sizes, weights, etc.

Watts	Lights	Watts on open secondary at 50 or 100 volts.	Weights	Full load efficiency	Regulation
500	10	20 to 23	49 lbs.	94.4	2%
1,000	20	20 to 24	87 lbs.	95.1	2%
1,250	25	22 to 27	93 lbs.	95.2	2%

FORT WAYNE ELECTRIC CORP.—This company's Wood transformer is shown in the illustration which represents their 37,500 watt transformer.

NEW YORK & OHIO CO.—The Packard transformer, made by this company, is distinguished by a circular coil, the primary and secondary being wound on a vulcabeston spool. The insulating material used in winding is a compound which makes the finished coil a compact mass, impervious to moisture, heat, over-load and lightning. The iron discs used on this coil have but one break in their circuit, making in this way a very perfect magnetic circuit.

The following table gives a very fair average of the efficiency and regulation of the Packard transformer.

The two latest types are type "G" and type "O." The type "G" is provided with self-contained fuse boxes of the single pole type, one on each side of the box, the plugs being very accessible from the outside. This type has also a changing block which can easily be gotten at by taking off the lid, by means of which the secondary connections are readily made for 100 or 50 volts as may be desired. This type can either be supported by the usual hanging straps or by bolting the same to cross arms through the lugs.

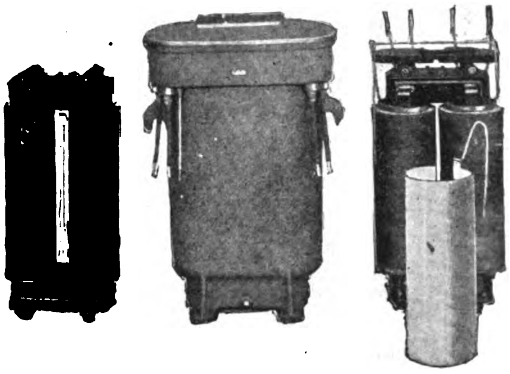
The type "O" transformer has been brought out on account of the increased demand for high potential transformers. The interior construction is practically the same as that of type "G," the change in shape having been made to secure better ventilation. There is a constant current of air passing around the outside edges of the inside of the case, and to this are exposed the iron discs of the transformer, which are not closely packed, but present a large radiating surface. The air space between the radiating discs also serves as a perfect insulator and prevents increased iron loss through ageing. Single pole fuse boxes are used in connection with this type and all secondary connections are readily made outside the box, the four secondary wires making possible either 50 or 100 volts, or 100 or 200 volts as desired. The hanging device is very simple, consisting of a single strap which can be bolted by means of lag screws to a cross arm or other support; the transformer case is provided with two eye bolts, one of which can be used in hoisting and into the other the hook of the hanging strap fits.

TABLE OF PACKARD TRANSFORMERS.

Capacity watts	500	1,500	2,500	5,000	10,000
Lights	10	30	50	100	200
Full load	92.7	95.9	96.1	96.9	97.0
¾ load	90.6	94.2	95.2	96.2	96.4
½ load	87.9	92.5	92.9	95.2	95.5
¼ load	82.9	90.1	90.8	91.4	92.5
Drop in volts at full load	2.1%	2%	1.8%	1.4%	1.5%
Iron loss in watts open sec.	21	40	61	89	120
Weight complete (lbs.)	48	101	142	241	503

Larger sizes show slight increase in efficiency over the above 200 light test.

GENERAL ELECTRIC CO.—This company's type H transformer is shown in the accompanying engraving. The core is built up of single rectangular punchings assembled into a rectangular bundle with notched ends. The bundle, compressed under great pressure, is compactly held by a casing of insulating material, around which is wound one-half of the low potential winding, leaving the toothed or notched ends only obtruding. Around this winding is an insulating wrapping and over it one-half of the high potential coil is wound. Two such cores and sets of coils placed side by side with the ends of the cores interlocked into another set of rectangular punchings, complete the interior construction of the transformer. To form as strong a barrier as possible against a high potential on the secondary, a protective device is added to the insulation. This is the so-called "earth shield," which is simply a sheet of copper placed between the primary and secondary windings and connected to earth. Thus even should the insulation between primary and secondary become pierced, this grounded shield would prevent any part of the secondary system being at any great difference of potential from the earth, and remove the danger to life and property due to high potential on the secondary winding.

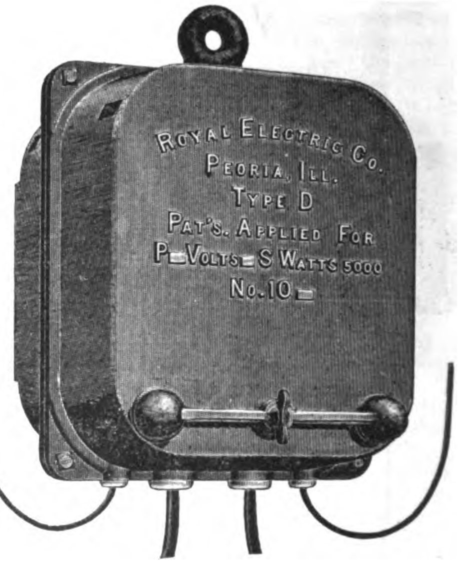


GENERAL ELECTRIC TYPE H TRANSFORMER.

The engraving shows a 10-kilowatt transformer of this type partially completed, the right hand core equipped with its shield and another shield standing in front of it.

ROYAL ELECTRIC COMPANY.—This company's transformers are built standard from 5 light to 200 lights; standard induction from 2,500 lines per square centimeter to 2,000. Tests show that the regulation is exceedingly close and the core losses are low.

The accompanying table gives the capacity in watts and approximate weights of their standard transformers, which are wound for 1,000 and 2,000 volts. Step-up transformers and step-down transformers of any capacity or voltage are built as ordered. One of the features is the hanging device, which is a separate plate easily attachable to a cross arm or pole, without necessitating handling the heavy weight of the transformer before the plate is secured. After it is put in



THE ROYAL ELECTRIC CO. TRANSFORMER.

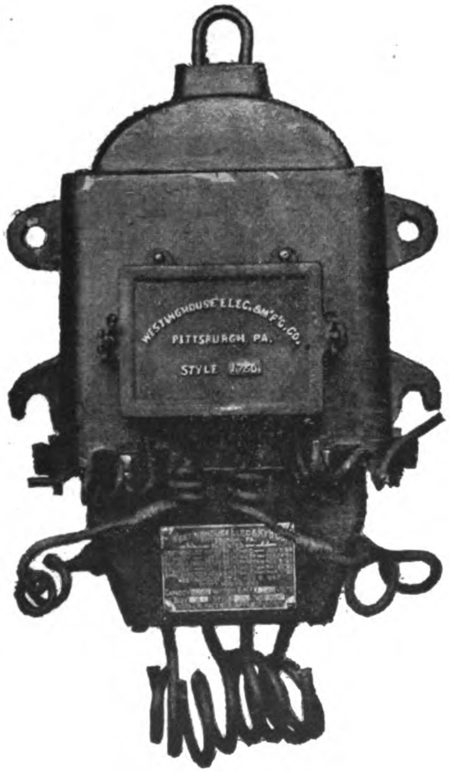
position, the transformer is raised and readily drops into position, without requiring any further attachment.

Capacity in watts.	Approx. weight.	Capacity in watts.	Approx. weight.
250	36	4,000	239
500	45	5,000	300
1,000	85	6,250	365
1,500	106	7,500	430
2,000	138	10,000	500
3,000	185	...	...

THE LAKON COMPANY.—This company has devoted its attention exclusively to the manufacture of transformers and accessories. Their standard type of apparatus is illustrated in the accompanying engraving. As will be seen the coils are subdivided so that they can be coupled up as desired for various potentials.

LAKON TRANSFORMER.

WESTINGHOUSE ELECTRIC AND MANUFACTURING CO.—The company's standard transformer is shown in the accompanying engraving. It is of the outdoor type, and the fuse block mounted directly upon it. It is noteworthy that the Westinghouse Company does not employ lead fuse wire for transformer currents over 10 amperes. Above that limit copper or aluminum wire of the proper gauge is employed as being more reliable than lead.



WESTINGHOUSE TRANSFORMER.

VINDEX ELECTRIC CO.—This company's transformer is shown in the accompanying illustration. The case consists of a cast iron top and bottom piece shrunk to a steel drum; by this method of construction a very light case is secured, the same being weather-proof and symmetrical in appearance, and the cost of it being materially reduced. All transformers are equipped with single-pole primary fusing devices.

Tests of a 50-light Vindex transformer show leakage and core losses to be 53 watts, and the regulation 2½ per cent. In a 100-light transformer the regulation was 2¼ per cent.

The weights and sizes of these transformers are as follows: 10-lights, 50 lbs.; 30-lights, 95 lbs.; 50-lights, 140 lbs.; 100-lights, 250 lbs.; 200-lights, 450 lbs., and 300-lights, 600 lbs.

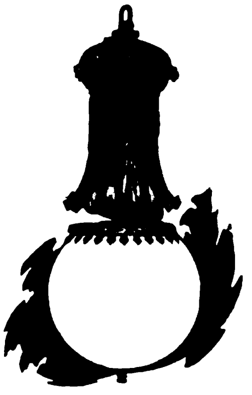
THE NATIONAL ELECTRIC CO.—This company manufacture the ring type of transformer illustrated in the accompanying engraving. The fuse box is cast directly to the transformer case.

VI.—ENCLOSED ARC LAMPS.

WHAT central stations managers were looking for for years has been accomplished,—a carbon with long life. But the method of its accomplishment is as remarkable as the results obtained. The fruitless attempts to secure a long burning carbon per se have been discounted by the simple expedient of enclosing the arc within a small globe and preventing the free circulation of air around it. The use of these enclosed arc lamps, as they are called, has spread with marvelous rapidity. Taking as they do 60 volts and over, they are specially economical to operate on incandescent circuits to which their use has thus far been chiefly confined. But it seems that this very fact has militated against their employment on series currents, though their economy in other respects is admitted.

ADAMS-BAGNALL ELECTRIC CO.—The accompanying cut shows the enclosed arc lamp of this company. The general appearance is the same as those for constant potential or constant current. It is short, and made in a large variety of finishes to match any suroundings.

This lamp, used on the common 110-volt circuits, burning 125 to 150 hours, according to the amount of light required, has already been described in these columns, but the less well known lamp to burn on series circuits has some points of interest. This lamp separates the carbons at starting to immediately give the proper voltage and when the carbons are consumed will reliably cut out like any open arc series lamp.



THE ADAMS-BAGNALL LAMP.

The function of "cutting out" in a lamp burning an open air arc is but a question of a few minutes after the carbons have ceased to feed. The same lamp burning an enclosed arc would not cut out properly, because the hour or two required would give time for the fine wire to overheat, and weaken its action so much that the lamp or inner globe would be damaged before cutting out took place. The loss in the dead resistance peculiar to arc lamps run from constant potential circuits, being saved where the lamps are run in series, added to the saving in carbons and trimming with all enclosed arcs, makes this type of arc lamp specially economical.

These advantages, it is claimed, will induce the winding of dynamos for the smaller ampere current most suitable for enclosed arcs. This small ampere current appears to be the only obstacle to the extensive use of series enclosed arcs. Of course, if glass-makers could produce inner globes that would not melt or break, users would not be compelled to observe the conditions for success now necessary, easy though they be, but with the existing quality of glass, the amount of light the public is accustomed to, can be reliably furnished. The most common mistake of users, strangely enough, is, that with a given size and quality of carbon, a lamp will not burn as long with six or seven amperes as it will with four or five. By using five to six amperes, and 65 to 75 volts in enclosed arc series lamps, the results desired can be obtained.

ELECTRIC ARC LIGHT CO.—The illustration represents the latest design of the "Pioneer" lamp. It is 32 inches long and especially adapted for low ceilings. The trimming or outer shell is made of brass, highly finished, with artistic ornamentation, and makes a very handsome appearance. It is intended for indoor purposes on direct current, constant potential systems and burns singly on 100 to 150 volts. It is also furnished for factory or mill purposes, the trimming or outer shell being a composition of metals, plain in design and painted black.

The length of carbons required is 9 inches upper and 4¾ inches lower, and will burn from 100 to 150 hours. It consumes between 4½ and 5 amperes, which is the standard, but higher or lower amperage lamps are also built by the company.

GENERAL ELECTRIC CO.—This company's enclosed arc lamps have recently been adapted for operation in series on railway and power circuits. These lamps are similar in design to the standard 100 and 150 hour lamps for 110 volt circuits. Five lamps are connected in series on 500 volts, each lamp taking 100 volts at its terminals.

The standard current is 5 amperes and a potential of 80 volts is required at the arc. The difference between the voltage at the arc and 100 volts at the terminals is taken up by a resistance self-contained in the lamp, which also acts as a regulator, steadying the potential at the arc. Two of these lamps are connected in series on 250 volts and operating under the same conditions. A cut-out is provided self-contained in each lamp, which operates automatically to cut out a lamp should it for any reason fail to burn. This is accomplished without interfering with the operation of the other lamps on the circuit.

The single solenoid lamp built by the company is for operation independently on 110 volt circuits and was designed to meet the demand for a short lamp. It operates under the same conditions as the regular 100 and 150 hour lamps, requiring 80 volts at the arc and 5 amperes. Its length over all is but 26 inches, and it is particularly suited to restaurants, hallways, vestibules and places where ceilings are low. This lamp has a life of 100 to 125 hours. In some cases a less powerful light is desired, and the lamp is, therefore, designed to operate also at 3 amperes. Under these conditions a smaller carbon is used and the life of the lamp is approximately 75 hours.

HELIOS ELECTRIC COMPANY make enclosed arc lamps for all constant potential circuits. The latest type of lamp is intended for power circuits of 220 volts or 500-volt railroad circuits, burning two in series on 220 volts, and five in series on 500-volt circuits. They are made to take from three to six amperes. The length from the top of the lamp to the bottom of the globe is but 32 inches for the five ampere lamps, which burn from 130 to 180 hours. The life of the three ampere lamps is about 100 hours.

To insure a maximum life of carbons, the lamp is provided with an automatic cut-out, which, when any individual lamp burns out throws in a compensating resistance equal to that of the arc, and insures the proper burning of the remaining lamps in series with it. This is especially important in factories where one lamp may burn out in the middle of the night while the other still has a half inch of carbon left, which will insure its burning until morning. The shunt magnets are wound so that if 220 volts are thrown on one lamp it will not burn them out. The lamps burn with a uniform brightness and will take care of a line variation of 20 per cent. without change in current. The cylinders are made so as to facilitate cleaning and trimming, which insures a minimum breakage.

IDEAL ELECTRIC CO.—The La Roche alternating current enclosed lamp of this company is designed to be connected directly across the constant potential mains and is built for any voltage from 80 to 110. Both upper and lower carbon feed at the same time, this maintaining the arc in the center of the globe and with 7½-inch carbons; the length of burning is 100 hours, and this with a lamp whose total length is but 30 inches. Each lamp is thoroughly tested in the laboratory before being sent out. The lamps manufactured by the Ideal Electric Co., of New York, are furnished in plain black, polished brass or ornamental brass cases as desired.

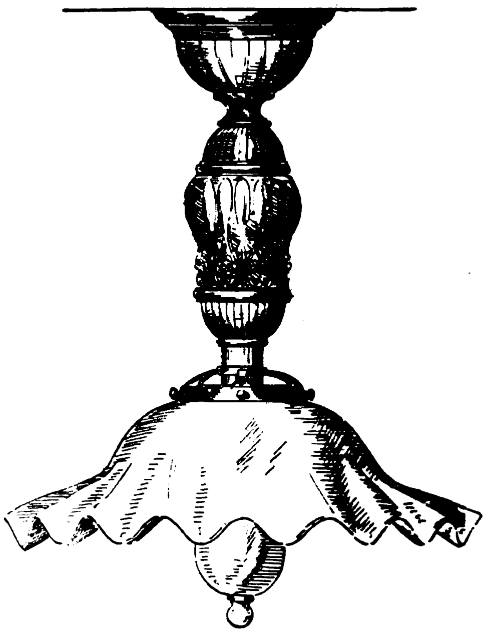
MANHATTAN GENERAL CONSTRUCTION CO.—The accompanying engraving shows the Manhattan "Standard" long burning enclosed arc lamp. The "Standard" lamp is 36 inches long, can be adjusted from 4 to 6 amperes, and is designed to burn singly on circuits of 100 to 125 volts. Under average conditions of burning these lamps require retrimming with a pair of ½-inch carbons about every 150 hours. This same type of lamp is made to burn 2 and 5 in series, respectively, on 250 or 500-volt circuits with the same life.

The "Junior" lamp is 24 inches long, can be adjusted for from 3 to 4 amperes, and is designed only for 100 to 125-volt circuits. The life of this type of lamp is 100 hours with a pair of ⅝-inch carbons.

The mechanism of the lamp is concentric to the central stem. The entire upper part of the mechanism is enclosed in the brass shell, the rheostat being placed in a canopy, at the top for the inside lamps, or at the bottom inside the outer globe for the outdoor lamps. The working parts of the lamp consist only of the clutch-pan and rings attached to the lower end of the solenoid core. The drawing up of this core causes the rings to clutch the carbon and thus establish the arc. The lowering of the core causes the carbons to feed as they are burned away.

The outer globe is secured in place at the upper opening by the yoke and there made air-tight with asbestos gaskets. At the bottom is a hand hole large enough to permit of trimming the lamp and cleaning the globe. This hand hole is yieldingly closed by a detachable dust pan.

INTERNATIONAL ARC LAMP CO.—The distinguishing feature of this company's Macintire lamp is its highly artistic design which adapts it to any interior, however ornamental. The entire lamp weighs but 5½ pounds, and contains no springs, adjusting screws or other delicate devices. The height of the lamp is only 16 inches, and its greatest diameter at any point is 3⅛ inches. The lamp operates on 5 amperes at a potential of 110 or 125 volts. The arc consumes 80 volts, and the carbons burn 150 hours.



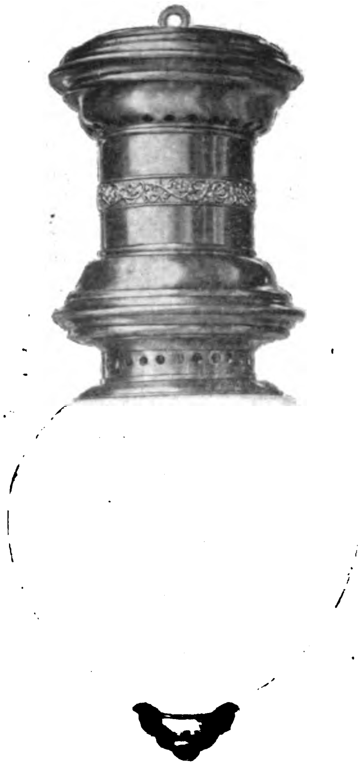
THE MACINTIRE LAMP.

THE PARAGON ARC LAMP COMPANY'S long-burning series arc lamp, for direct current high potential circuits, is shown in the accompanying engraving. This lamp is suitable for either interior or exterior lighting, and will work perfectly on circuits of from 6 to 10 amperes. The working mechanism is simple, strong, and durable, and not liable to get out of order. The lamp has a new globe-lowering device which is strong and simple, and will allow the globe to be lowered sufficiently so that the lamp can be trimmed easily.

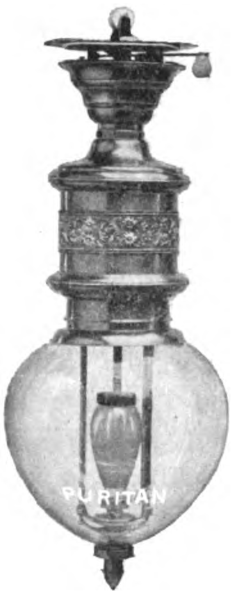
The lamp burns steadily throughout the entire life of the carbon, with a life of 100 hours per trimming. The lamp operates nicely on the current generated by any series arc machine.

PURITAN ELECTRIC CO.—This company's lamp is very simple in construction and short in length, measuring only 33 inches over all, and as shown in accompanying engraving is of highly ornamental appearance. The humming usual in the working parts of alternating lamps has been entirely eliminated, and the slight noise of the arc thoroughly subdued by the double enclosure.

This lamp burns for 100 hours with one pair of 7½-in. x ½-in. cored carbons. It is constructed for circuits of any frequency,

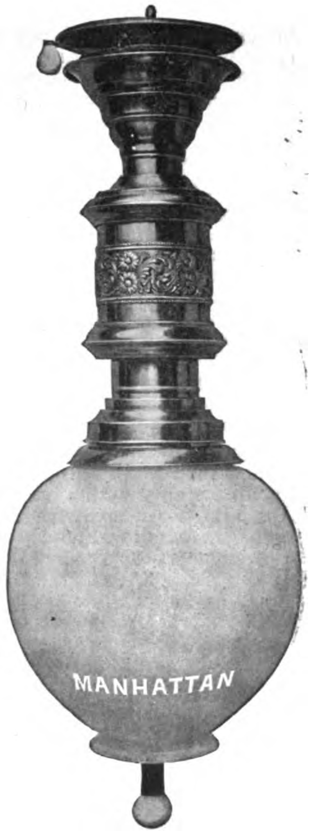


General Electric Lamp.



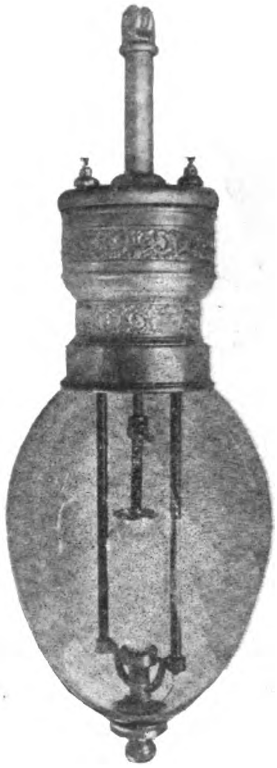
The Puritan Lamp.

The Helios Lamp.



The Manhattan Lamp

The Pioneer Lamp.



La Roche Lamp.

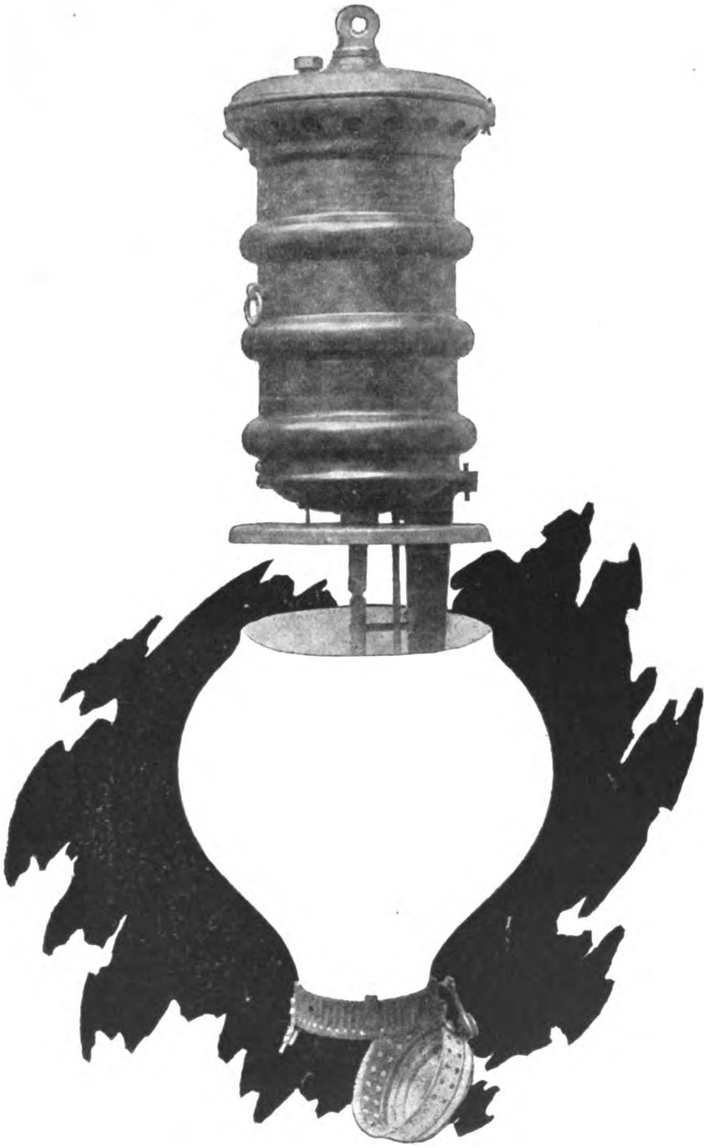
Paragon Enclosed Arc Lamp.

and secondary voltages between 100 and 120. Its current consumption can be adjusted from 4¾ amperes upward according to the candle-power desired. The Puritan enclosed arc lamp is also constructed for 6.8 ampere series arc, constant current, circuits taking 64 volts at the arc without any resistance and burning 100 hours, giving 2.000 candle-power.

NOWOTNY ELECTRIC CO.—In the design of this lamp special pains have been taken to avoid all rods, chimneys, clockwork, gearwheels, springs, and side rods and the outer globe-stand which cast shadows. The carbon is gripped directly without the intervention of any carbon rod; the clutch is composed of four porcelain balls, maintained in position by a retaining receptacle and performing all the functions of a ball-bearing, arc-maintaining device. The outer globe is supported by a ring at its top, which when lowered is held by three chains in such a manner that the globe can be raised or lowered without detaching it. The outdoor lamp shown is fully weatherproof, preventing any moisture from getting into the mechanism. It is furnished to consume 4 amperes, 4½ amperes and 5 amperes at 80 volts across the arc, with 110 volts on the line. The life of the carbons is from 125 to 150 hours.

WALKER COMPANY.—The accompanying engraving illustrates the Walker enclosed arc lamp for one hundred hours burning at one trimming. The same symmetrical shape of the casing and globe as used in the open arc system of the Walker Company has been preserved, and a slight change in the regulating apparatus together with the addition of the enclosing globe have been all that is necessary to create this new lamp. The Walker lamps, series constant potential, or enclosed, can be readily changed from one to the other by the substitution of a few parts. The mechanism of the lamp is simple and not liable to get out of order, and it has been subjected to exacting tests before being offered to the public. It was described in detail in a recent issue of the Engineer.

GENERAL INCANDESCENT ARC LIGHT CO.—This lamp is designed for use on constant potential circuits, the lamp burning singly with a current consumption of about 5 amperes. A single trimming with 12 by 7-16-inch upper and 5 by 7-16-inch lower solid carbons results in a life of from 100 to 125 hours. Fully equipped with such carbons the extreme length of the lamp is but 28 inches. The upper cap on the bulb through which the upper carbon passes centrally is an iron casting fitting the top of the glass and has its upper side coned so as to exactly fit the conical seat in the lower side of the mechanism base plate, when pushed up in position for operation. For feeding and regulating the operation of the lamp, a single concentrically placed series solenoid coil is used, acting on a hollow iron core, which surrounds the upper carbon.

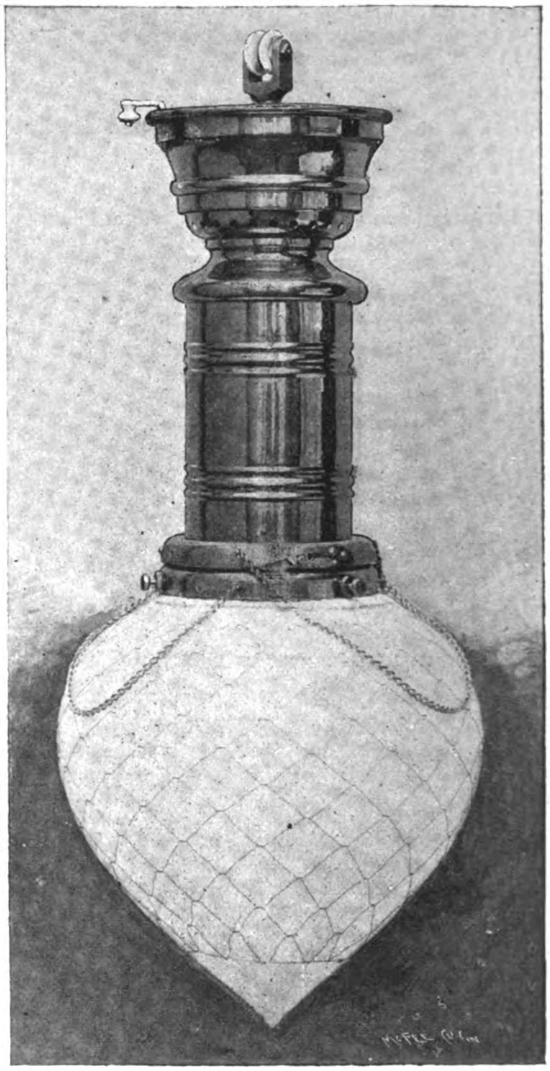


THE NEW WALKER ARC LAMP.

A telescopic tube arrangement allows the globe to readily slide down so as to clear the inner bulb and allow of the trimming of the lamp. When it is desired to obtain the maximum light and minimum height, the outer globe is dispensed with and in its place an opalescent reflecting shade is used fastened to the lower part of the casing, so arranged that the lamp only measures 24 inches.

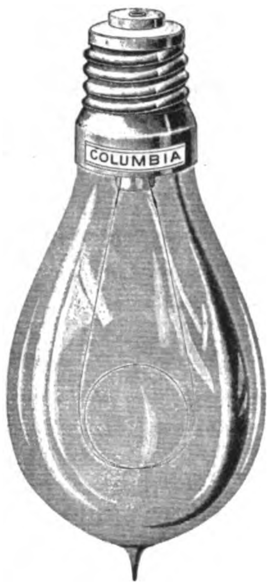
VII.—INCANDESCENT LAMPS.

THE incandescent lamp of to-day differs little from that of 1880, so far as essential principles are concerned. But in all that goes to make for economy and durability it has made great strides. Improved methods of manufacture have increased its useful life threefold and more, and its efficiency has been fairly doubled. The 50-watt 16-candle-power lamp is now the standard and will probably continue to hold its place for some time to come. The most recent tendency, however, is in the direction of the 220 and 250-volt lamp, and though this lamp is not yet quite as efficient as its low volt prototype, its use has some advantages which have begun to make for it an apparently lasting place in the art.

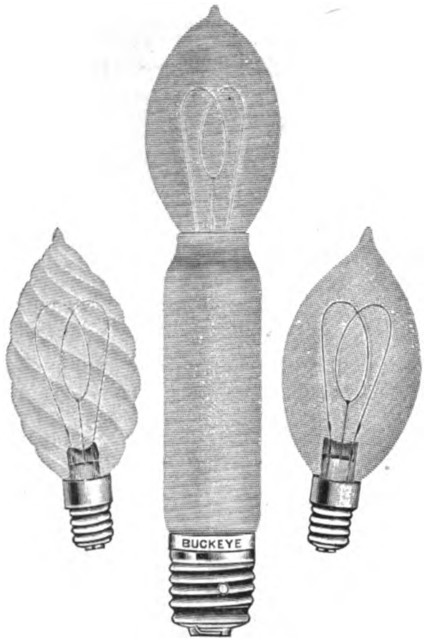


THE NOWOTNY LAMP.

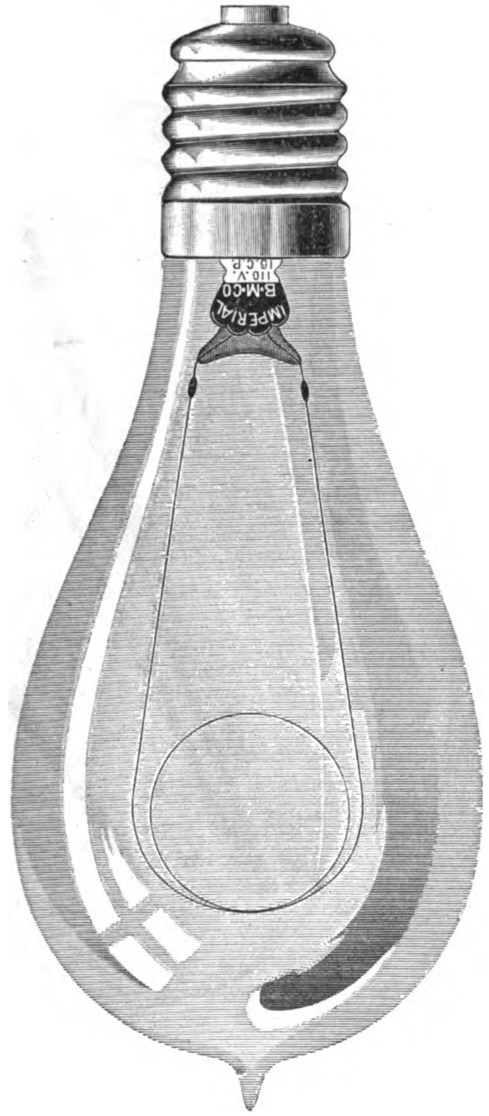
BUCKEYE ELECTRIC CO.—One of the latest novelties manufactured by the Buckeye Electric Company is shown on next page. The center figure shows a candle socket made of etched, opalescent glass which fits the Edison standard socket and carries a socket in the top in which candelabra lamps can be used. Only the glass portion is visible when the lamp is in place, and, when lighted, it presents the appearance of a



Columbia Incandescent Lamp.

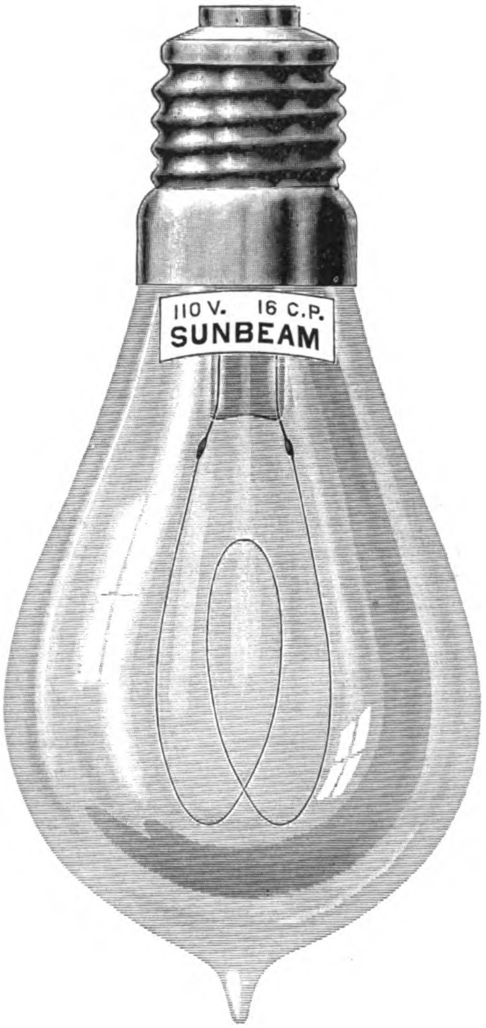


Buckeye Candelabra Lamps.



IMPERIAL
B·M·CO
110 V.
16 C.P.

Bryan-Marsh Lamp.

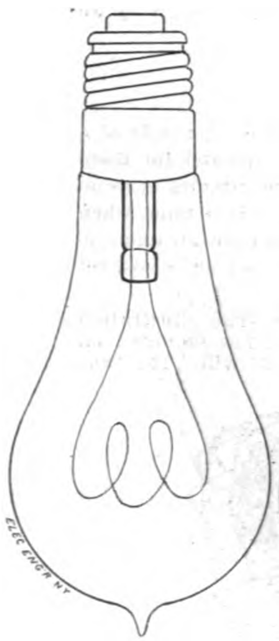


Sunbeam Lamp.

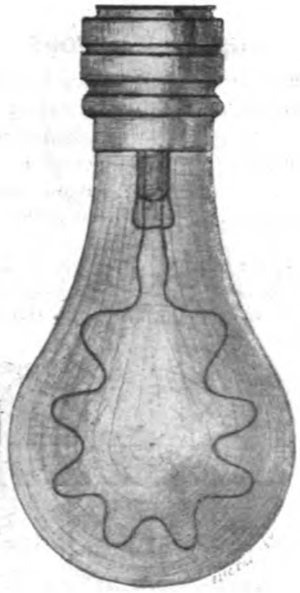
burning candle. The side figures show two of the many styles of lamps that can be used in the candle. A distinctive feature is that the lamps are made not only of low voltages, but for 100 to 120-volt circuits, thus obviating the inconvenience of using two lamps in series.

The standard Buckeye lamps range from 6 to 100 candle 24 candle power, 3.1 watts per candle.

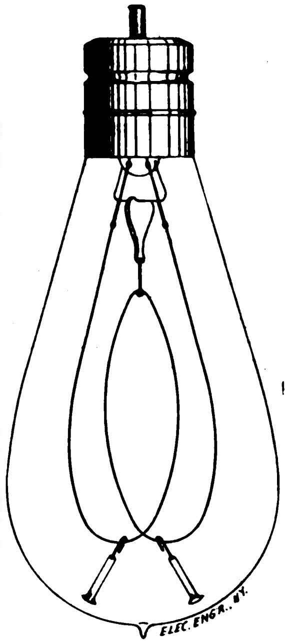
GENERAL ELECTRIC CO.—The accompanying engraving shows in exact size the latest type of the standard new type Edison lamp. This type of lamp is furnished in voltages from



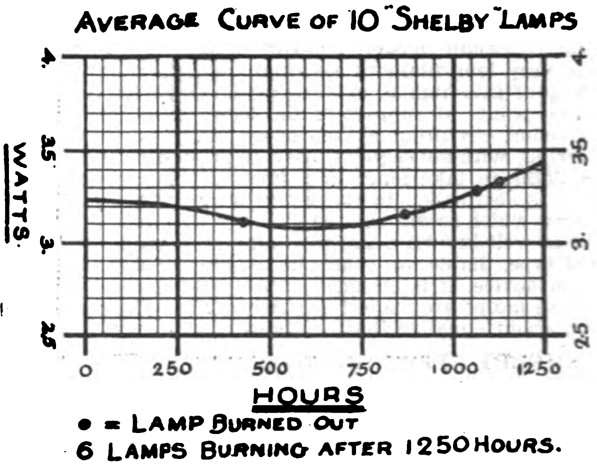
WORMLEY.



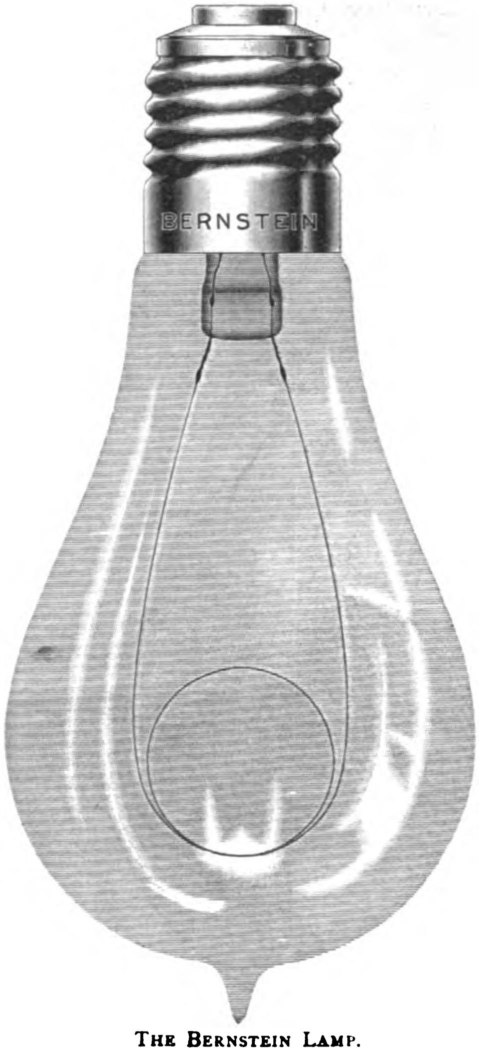
THE SHELBY STAR.



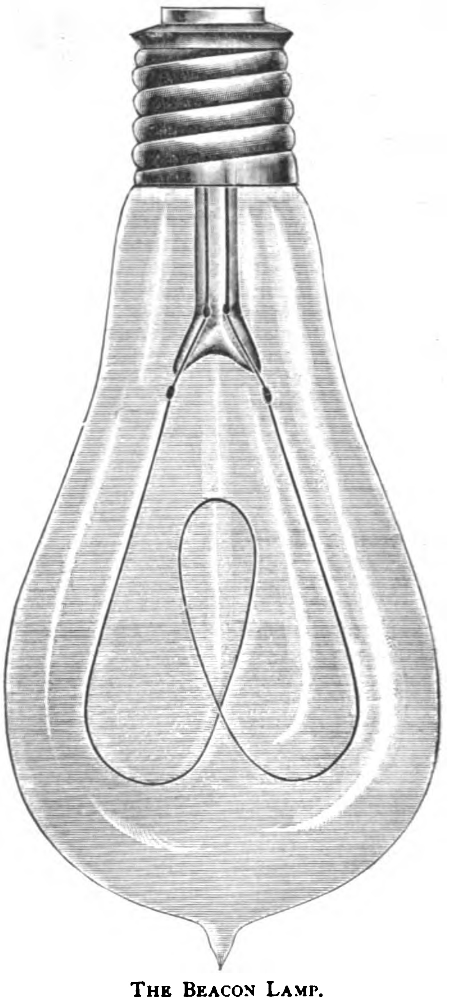
SAWYER-MAN.



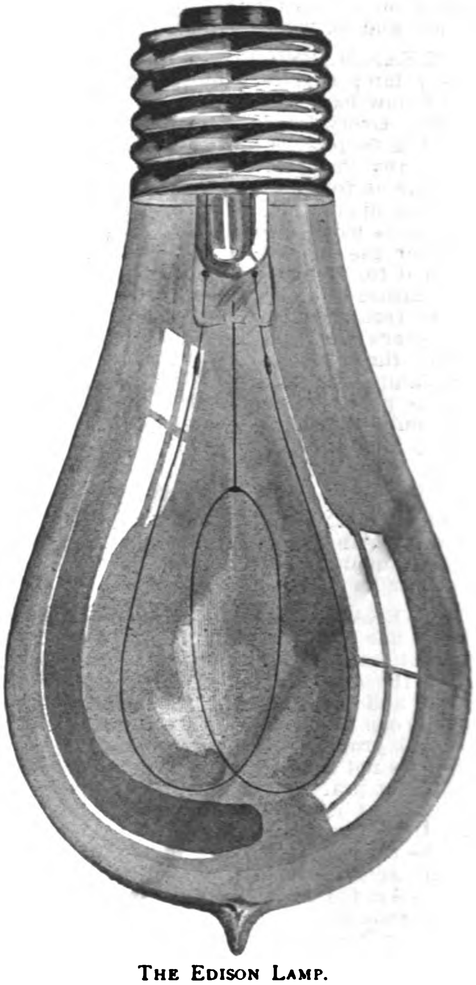
SHELBY INCANDESCENT LAMP CURVE.



THE BERNSTEIN LAMP.



THE BEACON LAMP.



THE EDISON LAMP.

90 to 125 volts, and in 10, 16, 20 and 24 candle power, and of the following efficiencies:

24 candle power, 3.1 watts per candle power.
20 candle power, 3.1 and 3.6 watts per candle.
16 candle power, 3.1, 3.6 and 4 watts per candle.
10 candle power, 4 watts per candle.

The engraving illustrates the mechanical features of the lamp, among which are the following: The carbon filaments are wound in oval form, filling and fitting the bulb with a bright sphere. The carbon filaments are anchored to the stem of the lamp; the anchor holding the filament securely in position, prevents it from touching the glass, avoids interlocking of the branches of the filament and overcomes vibration. The bulbs are thoroughly uniform in size, all bulbs being molded to one standard gauge.

These lamps, manufactured by the General Electric Company, are all exhausted by the new process of chemical exhaustion, as described in The Electrical Engineer of March 31.

SAWYER-MAN CO.—The old Sawyer-Man lamp is so well known that any description of standard types is unnecessary. We give herewith an illustration of the latest form of 16, 20 and 25 candle power, 220-volt lamp. It will be noted that the very long filament essential for a thoroughly satisfactory lamp of this high e. m. f. is rendered perfectly stable by the three points of support of the loop. This renders impossible the short circuiting of the carbon due to excessive vibration or jarring, with subsequent disaster to sockets and fittings which is liable to take place in a lamp not so constructed. Attention is also called to the glass bridge between the leading-in wires which serves as a support for the anchor from the stem. As is well known a 220-volt lamp is, if made after the standard type, liable to short-circuit across the leading in wires. This device, it is claimed, entirely prevents any such action. These lamps are made from 200 to 250 volts, the efficiency being about equal to that of standard voltages.

SHELBY ELECTRIC CO.—The design illustrated is one of many that are made by this company, and is called the "Shelby Star." The diagram shows the average curve of ten Shelby lamps as tested by Charles F. Stillwell.

JAS. C. WORMLEY & CO.—This is a double coil lamp. This form was adopted as the company's standard commercial lamp for the reason that it can be used on steamships, cars and other places where great vibration is found, with the best satisfaction. The spiral spring effect is claimed also to have the advantage over straight and single coil filaments for horizontal use as the filament will not sag.

These double coil filament lamps have an efficiency of from 3 watts per candle power upwards and are made from 8 to 50 candle power, in voltages of 100 and over. The company guarantee on 3½-watt lamps of this type an average life of 800 hours and on 3-watt lamps 600 hours.

BRYAN-MARSH CO.—While it is not yet possible to make every lamp so it will burn out after the same life, the company now have reached as near that condition as it is possible to do. Every Imperial lamp, before the photometric measurement in factory, is burned a sufficient length of time to determine any imperfection in the filament or the vacuum. This is done as follows: After the lamps come off the pumps, they are put upon a spark coil to determine the degree of vacuum, and as is usual, poor lamps are weeded out.

After the spark coil test the lamps are put on racks, and burned for from ten minutes to half an hour (depending upon the nature of the filament), to see if any occluded gases will come from the filament. They are then again passed over the spark coil, and any filaments which are not perfect, and which throw off gases, are weeded out. In consequence, when the lamps are taken to the photometer to be measured, they are as nearly perfect as it is possible to make them, and are not only regular in candle power, but are of uniform brilliancy and life.

The company's lamp is illustrated in the accompanying engraving.

THE BERNSTEIN ELECTRIC CO.—The illustration shows this company's regular coil filament 16 candle-power lamp. The company makes a large variety of lamps in all voltages and candle powers.

SUNBEAM INCANDECENT LAMP CO.—This company's lamp has been recently reconstructed and a new and improved seal has been adopted, but the principal improvement is in the shape of the coil, which gives the best diffusion of light, and is so constructed as to be self-supporting. It cannot droop against the glass. The filament is subjected to a special process of "ripening," the result being that the filament is not further changed by either heat of cold, and it remains at practically the same resistance throughout its entire life; or at its normal voltage it will, during its whole life, give its original candle power. A considerable more time is given to the exhaustion of the Sunbeam lamps than it usual in lamp manufacturing. The Sunbeam Company has made a specialty of its 4 c. p. lamp, taking 18 watts, and of these a great many thousands are in use in signs all over the country. It also makes a 2 c. p. night lamp and all other standard candle powers up to 150 and for any voltage up to 250.

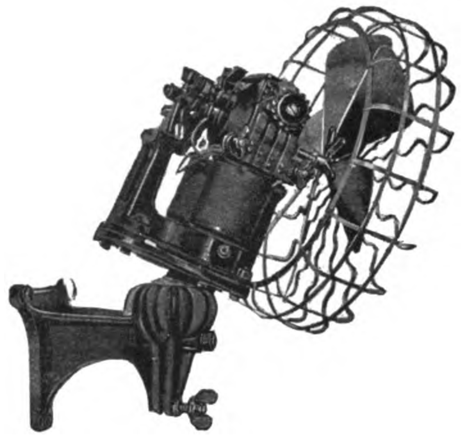
THE BEACON INCANDESCENT LAMP CO.—The engraving shows this company's lamp full size. Special features are embodied in the mount. In addition to the standard 16 c. p. lamp the company manufacture a large variety of special types from 1 candle power up to 500 c. p.

THE COLUMBIA INCANDESCENT LAMP CO.—This company manufacture lamps for all varieties of service. Their standard 16 candle-power lamp illustrated is made in efficiencies from 50 to 60 watts according to demand. The filament is of the cellulose type and is joined to the leading-in wires by an electro-plated joint.

VIII.—FAN MOTORS.

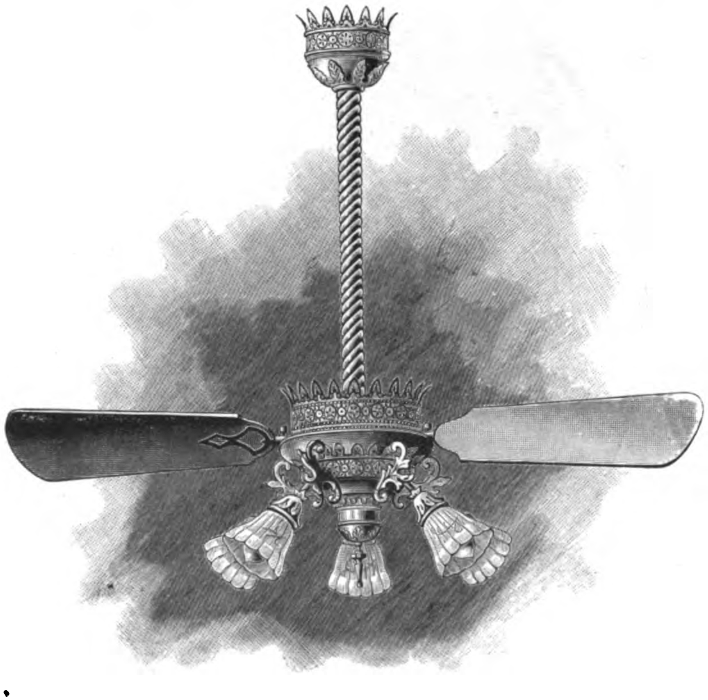
THESE welcome little blowers have become the staple of a large and increasing trade. The heavy demand for them has called for designs to go on all classes of circuits even on 500-volt motor circuits. The time seems not far distant when they will be as common as push buttons, and not an inappreciable part of the day load of some central stations is now set down to their credit.

CROCKER-WHEELER ELECTRIC CO.—The illustration represents this company's standard type of fan mounted on bracket so that the breeze may be directed at will. The fans are built in capacities of 1-6 and 1-12 horse power and for all direct current voltages up to 500.



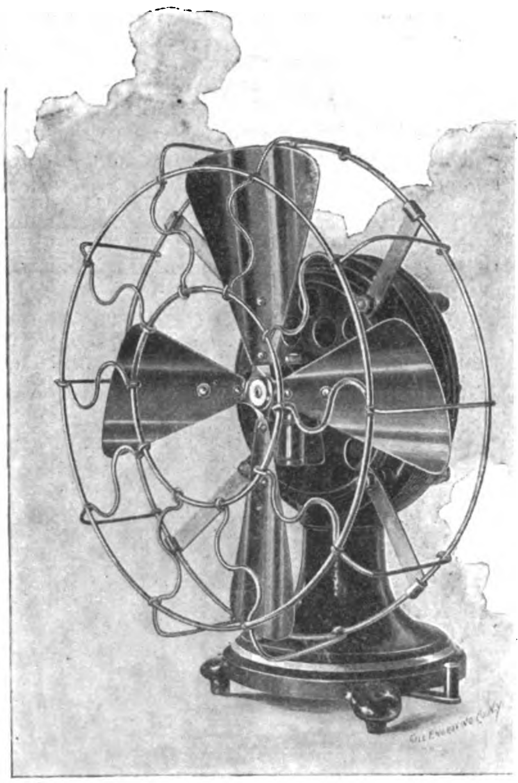
CROCKER-WHEELER FAN MOTOR.

DIEHL MANPFACTURING CO.—The electrolier and desk fans of this company, illustrated herewith, are adapted for all direct currents from 125 to 500 volts, and for direct arc currents for 6.8, 9.6 or 18 amperes. On 500-volt circuits they may be operated successfully singly or in series of two fans, each wound for 250 volts; three fans each wound for 170 volts, or four fans each wound for 125 volts.

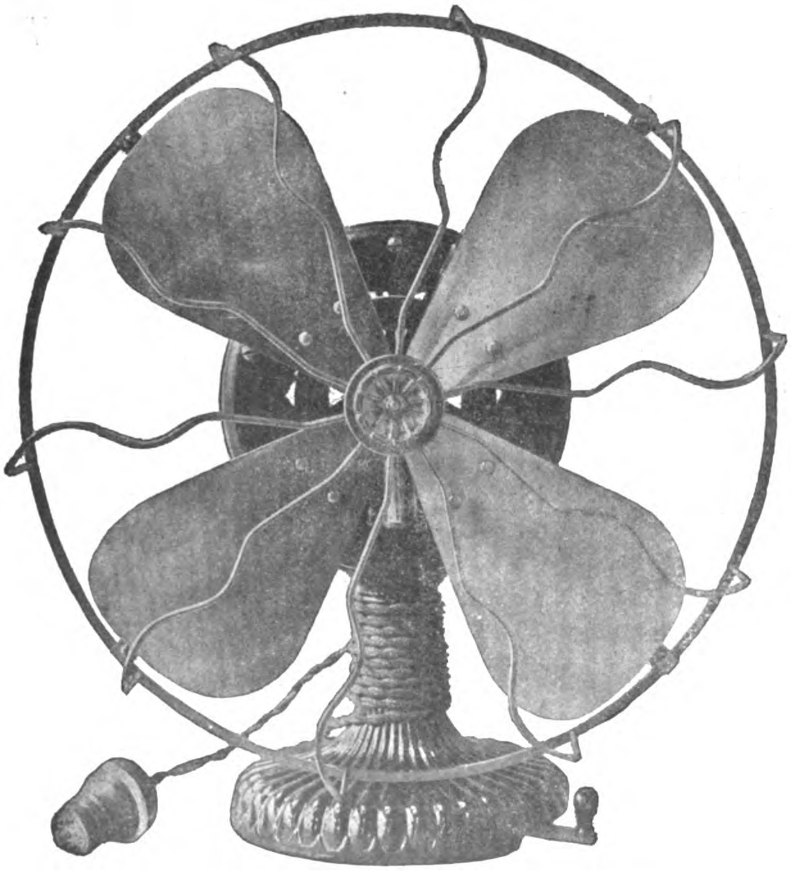


DIEHL CHANDELIER FAN.

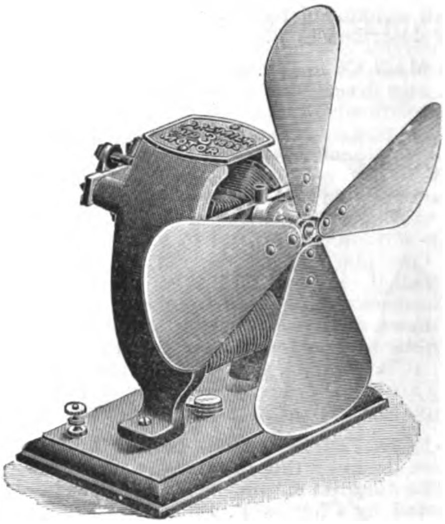
Each fan contains its own motor, directly coupled to the fan shaft, and is provided with an improved oil cup.



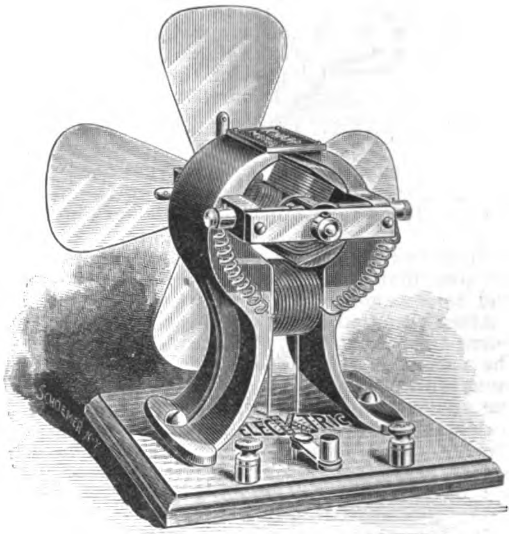
Lundell Alternating Fan Motor



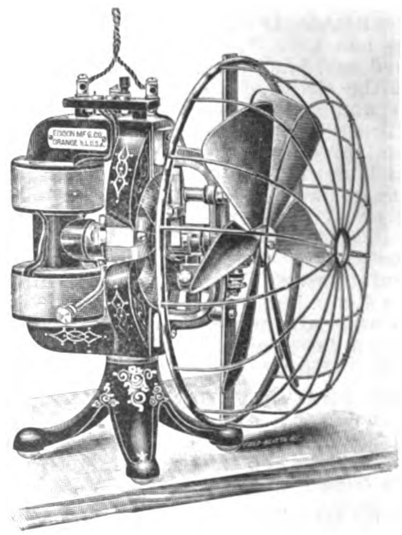
Westinghouse Alternating Fan Motor.



Premier Battery Fan Motor.



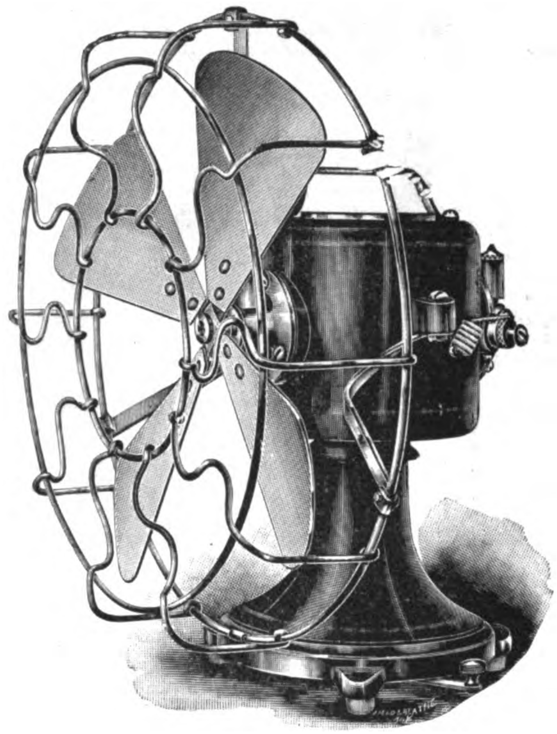
Knapp Battery Fan Motor.



EDISON MFG. CO.
ORANGE N.J. U.S.A.

Edison Fan Motor.

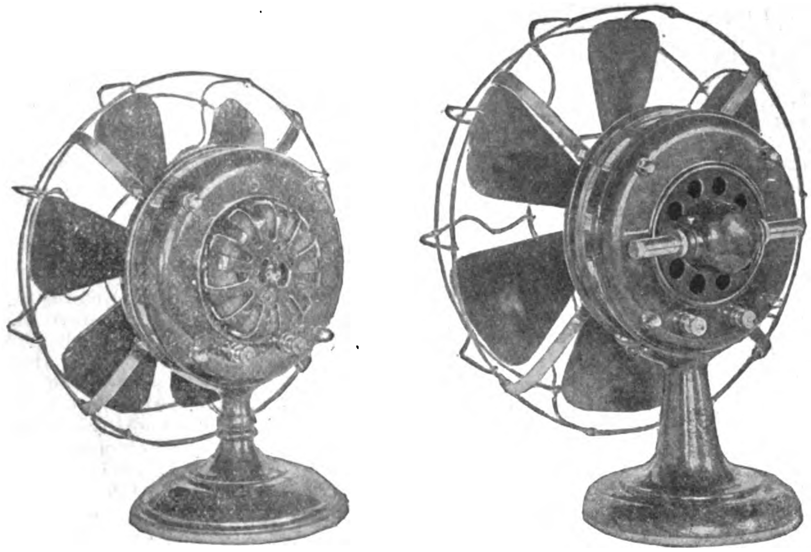
EDISON MANUFACTURING CO.—The iron clad outfit of this company carries a 7-inch fan and is now provided with a guard. The batteries operating this motor consist of three Edison-Lalande cells type "S," and the motor runs at about 1,200 r. p. m. The battery will run the fan for 150 hours before requiring to be recharged.



WILLIAMS FAN MOTOR.

The 9-inch Edison fan motor outfit, made by the same company has been considerably improved this season. The motor is more efficient and now runs the fan at about 900 r. p. m. on a little more than 2 amperes of current, when using the battery supplied with this outfit which consists of four Edison-Lalande cells type "S" in polished oak box. The motor is provided with self-oiling bearings.

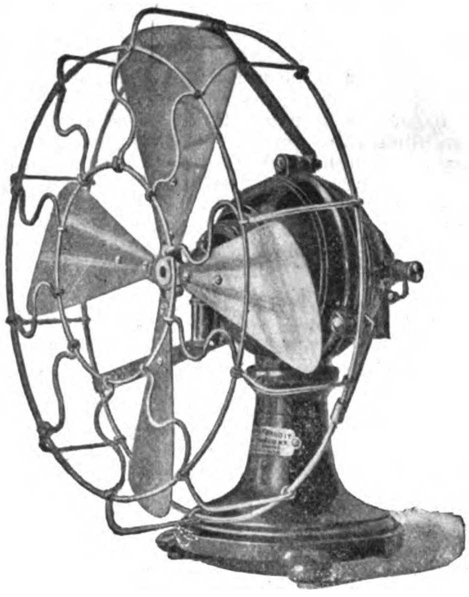
This company has made a new departure this year, in bringing out a 9-inch fan motor to run on the 110 to 120-volt direct current. This motor is similar in construction to the 9-inch Edison battery fan motor, but is wound for the electric light circuit, and will run right across the line. It is provided with 3 speeds, namely 1,400, 1,700 and 2,100 r. p. m., the watts used at these three speeds being only 36, 48 and 60 respectively.



GENERAL ELECTRIC ALTERNATING AND DIRECT CURRENT FAN MOTORS.

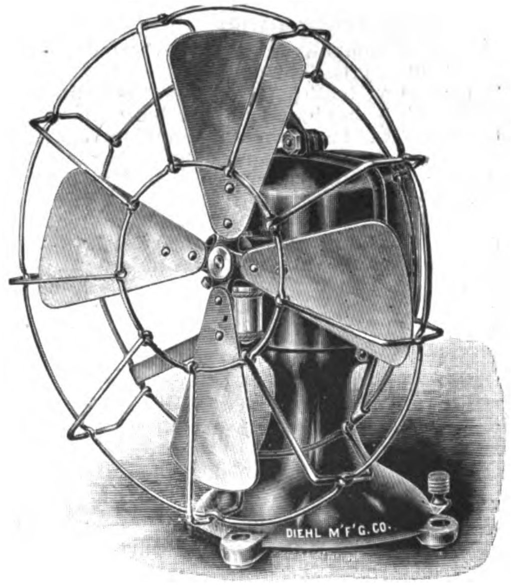
GENERAL ELECTRIC CO.'S '97 model fan motors are shown in the accompanying illustrations. In addition to the alternating type, they have a motor for use on direct currents. In general appearance both motors are similar to earlier productions, retaining their characteristic compactness and simplicity while possessing definite features of improvement.

The alternating current fan motor is made for either 60 cycles or 125 cycles. It contains a speed regulating device consisting of an inductive resistance operated by a three-point snap switch capable of giving full speed and half speed, the third position of the switch cutting the motor out of circuit. This controlling switch not only permits a change of speed, but allows the motor to be wired directly to a circuit without the introduction of a lamp socket and plug connection.



LUNDELL FAN MOTOR.

The electrical design of the motor is essentially the same as the '95 and '96 models. The field core is a ring of iron punchings upon the inwardly projecting teeth of which the field coils are placed. The armature has no insulated wire, but consists of the customary laminated core through which, near the periphery, bare copper rods are run, their ends being riveted to copper discs at the ends of the core. As the rotation is produced by inductive action, no commutator or brushes are required. This permits the armature core to overhang the bearing to such a degree that together with the fan, a bal-



DIEHL M'F'G. CO.
DIEHL FAN MOTOR.

ance is effected in the single bearing of the motor. This bearing is long and is provided with a self-oiling device so that it does not heat. By this method of lubrication the flying of oil is prevented.

The direct current fan motor has a single self-oiling bearing. The commutator is completely enclosed and the brushes are small carbon rods encased in tubes which may be easily unscrewed for inspection. The motor circuit may be opened and either half speed or full speed obtained by a regulating device and switch located in the base. The fan is 12 inches in diameter.

INTERIOR CONDUIT AND INSULATION CO.—The company manufacture a large variety of direct and alternate current outfits, of different types such as desk, bracket and suspended, fans of the propeller type. Also ceiling and column fans. The illustration shows the direct current desk outfit. This has starting and regulating switch giving three speeds, viz., 1-12 horse power, 1,800, 1,400 and 1,100 r. p. m., 1-6 horse power, 1,500, 1,200 and 800 r. p. m. at 110 volts. They are provided with self-oiling and self-aligning bearings, and all outside brass fittings polished or nickeled. The company also manufacture a variety of ceiling fans.

THE KNAPP ELECTRIC AND NOVELTY CO. manufacture small battery motors designed for driving fans, experimental work, and running light machinery. Pulleys are attached to each of these motors and switches to the three largest sizes.

The name of the smallest type is "Little Hustler," being a five-inch fan driven by a 2-volt battery.

Type B. drives a four blade 6-inch fan on two to four volts. Type C an 8-inch fan on two to six volts and type D a 10-inch fan on two to eight volts. Fan guards are furnished with the two largest types.

M. R. RODRIGUEZ.—The accompanying table gives the details of the various sizes of the "Premier" battery fan motors:

No. of Motor.	Weig't	Height	Speed Without Fan.	Diam. of Fan.	Speed with Fan.	No. of Cells.	Voltage.	Amp. required
2	38 oz.	4½ in.	1,600	6 in.	900	1	2	.5
3	72 "	6 "	2,700	6 "	1,400	2	4	.5 to .75
3	72 "	6 "	3,000	8 "	1,900	3	6	.75 to .1
3B	94 "	7 "	3,000	10 "	1,400	3	6	1 to 1.5

Taken with freshly charged primary cells, "Premier" No. 2 Battery, one charge will operate motor from 20 to 40 hours, at an average cost of 1 cent per hour. The manufacturer recommends storage batteries, when a steady current is desirable, and charged from bluestone cells.

THE WESTINGHOUSE ELECTRIC MANUFACTURING CO.—This company's fan is of the induction alternating type. The field ring is built up of thin soft steel plates, with inwardly projecting teeth to which the field winding is applied. The armature is laminated, being built up of steel discs, slotted to receive the bare copper conductors. No insulation is needed; consequently there is nothing to burn out. The motor has neither commutator nor brushes. The bearings are self-oiling and self-aligning, thus reducing the friction to a minimum. They are provided with oil chambers, requiring but one filling for the season. The motor carries a 13-inch four-blade fan which is protected by a substantial guard. A switch in the base permits of its being run at two speeds or cut out at will.

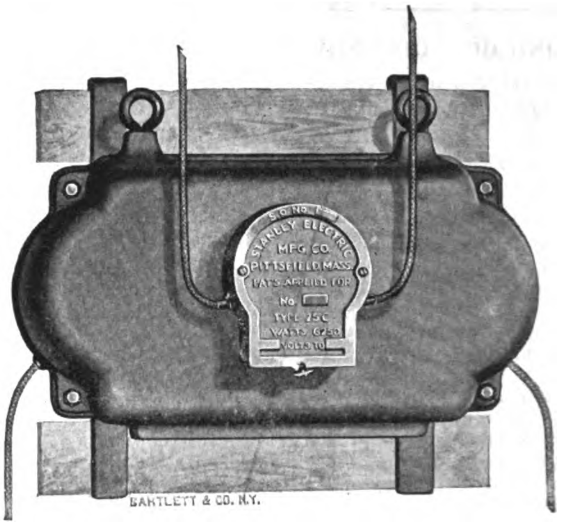
These motors are manufactured for use on circuits of 7,200 and 16,000 alternations per minute and for 50 and 100 volt service.

J. P. WILLIAMS.—The illustration represents the Paragon iron clad fan motor. It is also designed as a bracket motor, which can be fastened to a side wall and placed in any position by means of a thumb screw. The fan of this make called the "White-Flyer," is finished in white and gold.

THE EAST ORANGE FAN CO.—This company are manufacturers of high-grade electric fans of all types, and are about to erect a power plant to be operated by water power, in order to meet the demand of a rapidly increasing business. The fan built by this company is made of steel with multipolar fields, ironclad armature and drop-forged commutator. The fans are very light in weight and are built for three speeds and for 110, 220 and 500 volts, and can be used either for desk or wall. The bearings of these fans are self-greasing (no oil being used), which especially, as regards the wall type of fan, is a decided improvement, as whenever it is required to tilt a fan, where oil is used, it is universally found that the oil will run out at the end of the bearings.

ADDENDUM—TRANSFORMERS.

STANLEY ELECTRIC MFG. CO.—This company's transformers are designed particularly for high efficiency over a wide range of loads and for safety and reliability. Their efficiency at full load, depending upon the size, is, for full load, 97½ to 93 per cent.; half load, 97.1 to 90 per cent.; quarter load, 96 to 85 per cent. The variation of the secondary e. m. f. between no load and full load is from 1 to 1½ volts on 50-volt circuits, depending on the size of the transformer. The insulation is such that the coils can be submerged in water without injury. Both coils form a solid mass with the insulation and are thoroughly protected from contact with the iron core.



STANLEY CO.'S TRANSFORMER.

TEST OF AUTOMATIC CIRCUIT BREAKERS BY THE EDISON ILLUMINATING COMPANY OF NEW YORK.

CONSIDERABLE interest has recently been taken in the working of automatic circuit breakers and motor starting rheostats, and in order to determine which of the devices on the market were of the most satisfactory character, the Edison Illuminating Company, during the past week, invited all the manufacturers of these devices to make a test at their Duane street station, with the object of determining their various merits for their own satisfaction, and that of the Board of Fire Underwriters. The following companies had their specialties on exhibit, and the tests were made under the superintendence of Mr. Arthur Williams, chief of the Inspection Bureau of the Edison Illuminating Company, and Mr. J. Van Vleck, chief of the engineering department: American Rheostat Company, C & C Electric Co., Automatic Circuit Breaker Company, Cutler-Hammer Manufacturing Company, American Electric Heating Corporation, Ward-Leonard Electric Co., Excelsior Electric Co., General Electric Co., Cutter Electrical and Manufacturing Co., Crocker-Wheeler Electric Company and D. and W. Fuse Company, of Providence. Mr. Williams made a short speech before the tests were commenced, explaining the object for which they were made, and thanked the manufacturers for putting their apparatus at disposal, and also thanked the inspectors of the Fire Department for their kind attendance. Mr. Van Vleck then went on to explain the object to be obtained by a starting box, and stated that the tests would be of three characters. First, to break current at a standard amperage; secondly, to break promptly in case of an interrupted current, and, thirdly, to break the current in case of overload. While we are not yet in a position to give the actual particulars of the tests, it is interesting to know that they were all of a most satisfactory character, that all present were greatly interested, and that the investigation brought forth a valuable amount of information on points hitherto obscure.

The Edison Illuminating Company also served a slight repast, which had been cooked in their own electrical kitchen. The automatic circuit breaker tests made were of the most elaborate kind, and extended over a period of about three days.

TELEPHONY AND TELEGRAPHY

MEETING OF INDEPENDENT TELEPHONE COMPANIES.

A MEETING of independent telephone manufacturers took place at the office of the Western Telephone Construction Company, Chicago, on June 1st. Among those who were present were H. A. Coit, Missouri Telephone Manufacturing Company, St. Louis, Mo.; C. H. North, North Electric Works, Cleveland, O.; F. F. Sapp, Connecticut Telephone and Electric Company, Meriden, Conn., and others.

Mr. J. E. Keelyn, having been appointed chairman of the meeting, some matters of business were transacted, the most important being the drawing up and adoption of the following resolutions:

That the manufacturers of independent telephone apparatus should form a harmonious association for promoting the mutual interests of its members.

That the independent telephone manufacturers establish a bureau of information to further the development of the independent movement and disseminate data and statistics counteracting the false or misleading statements sent out in the interests of the Bell monopoly.

That the manufacturers of independent telephone apparatus should make an effort to aid in extending the influence and strength of the National Association of Independent Telephone Exchanges and tender its hearty support thereto.

It was also agreed upon to attend along with the independent telephone companies the convention which will be held in Detroit on June 22, and afterwards to hold another meeting in Chicago on June 25.

DAMAGES FOR TELEPHONE POLE ENCROACHMENTS.

A special dispatch from Medina, N. Y., of May 28 says: The first of the series of suits brought by farmers in Western New York against the Bell Telephone Company because of the setting of poles along the roadway, has just been decided by commissioners in Medina. The verdict was in favor of Joshua Sharpsteen against the company for about $150, which included the costs of the action. Twelve poles were set in front of M. Sharpsteen's premises and he refused to accept the $25 offered by the company in settlement of his claim. The case was argued before Judge North, of Batavia, Wells D. English, of Albion, and Charles Baker, of Shelby. More than 1,000 cases are pending in Western New York against the Bell Telephone Company and the American Telegraph and Telephone Company on these grounds, although many of them will be settled at the rate of from $4 to $5 for each pole with extra damages in special cases. Other cases will come up at once. Austin Wadsworth, of Genesee, has a claim for damages on 1,000 poles set in front of his many farms.

A LESSON FOR A TELEPHONE SUBSCRIBER.

So strict has the telephone company become here, says the "Pittsburg Dispatch," that almost every instrument is a pay station and the law forbidding the free use of private instruments by anyone but subscribers is generally enforced with the utmost rigidity. This is, of course, especially the case with instruments which have long distance connections, every call over which is charged to the renter's account. It is that which makes the joke on the District Attorney especially choice. He was buncoed beautifully a day or two ago by a stranger whose unctuous politeness won him the privilege of using the city's instrument. The stranger entered the sound-proof box and occupied it for several minutes. Nothing was thought of that, as the service often involves delay and the number called might have been engaged, but there was wrath when Central called up just after the stranger had vanished and announced, in conformity with rule and custom, that there was a charge of $6.40 for calls to Buffalo. Now the District Attorney doesn't know what to do about it.

STRANGE TELEPHONE TALK IN ST. LOUIS.

A special dispatch from St. Louis of May 29 says: "We don't have to go into the anti-Bell combine to secure long distance connections," said Manager Hopkins J. Hanford of the Kinloch Telephone Company to-day. "The Western Union Telegraph Company is prepared to start a long-distance telephone system that will be far superior to any the Bell company can ever have. The Western Union for many years had a contract with the Bell company by which the Western Union agreed to stay out of the telephone field. That contract expired last fall. In anticipation of its expiration the Western Union for ten or twelve years has been stringing copper wires for metallic circuit telephones, and now it has 19,000 stations connected by these copper wire circuits. The Bell company has only about 1,100 long distance stations.

"The Western Union can put its long-distance telephone system in working order by simply attaching receivers and transmitters to the wires it uses for transmitting messages. By the time the Kinloch company is ready for business the Western Union will have its long-distance telephone service in operation, and we will have no trouble securing their service."

THE USE OF TELEPHONES BY ROYALTY.

AN unaccredited item in one of the daily papers gives the following information, which is alleged to be correct, about the use of the telephone by the "crowned heads of Europe:"

Now that Queen Victoria has at length permitted the installation of the telephone at Windsor Castle, Osborne house, Balmoral and Buckingham palace, there is not a sovereign in Europe who does not utilize this instrument for communicating royal and imperial wishes, as well as commands to subjects and officials. Even the Pope, who has decided that, while a confession may be heard over the telephone, the priest cannot use the wire for the purpose of granting absolution, has had a receiver installed in his private apartments by means of which he often communicates with the Propaganda Fide, which is situated on the other side of the Tiber and at a considerable distance from the Vatican. It is generally his valet, Cintra, who does the talking over the wire for him, but he occasionally speaks over it himself, and only the other day, when a Jesuit priest was taken suddenly ill during a private audience, the Pope rushed to the little red-lined booth and personally called up the Jesuit college, says an exchange.

King Leopold is enabled by means of the telephone, to communicate with his ministers at Brussels without leaving his palace at Laeken or his marine residence at Ostend. When, a year ago, the little King of Spain was prostrated with the measles, and secluded at one end of the huge palace at Madrid, the Queen Regent was able to hold intercourse with him, located in a distant wing of the edifice, not only daily, but almost hourly, over the wire.

Queen Victoria, however, is so ultraconservative that it is most difficult to get her consent to any modern innovation, and it was only two years ago she permitted the installation of electric light in the state apartments of Windsor. Previously electricity, as well as gas, had been uncompromisingly barred from her private apartment. Yet it is almost impossible to exaggerate the importance of thus placing the various residences of the Queen in telephonic communication with London, as far as the transmission of official business is concerned.

Until now, whenever the Queen was desirous of consulting one of her constitutional advisers upon any point or when any cabinet minister had some matter of urgency to impart to Her Majesty the unfortunate dignitary had to travel all the way from Windsor to Balmoral—a twenty-four hours' journey—or to Osborne, which entailed a sea trip across the stormy Solent, very often only for the sake of ten minutes' talk with the sovereign. Then, too, Lord Salisbury and even Mr. Chamberlain, both of them busy men, have had to spend a good deal of their time explaining matters to the Queen in writing.

In the same proportion that the Queen is old-fashioned in her views, in her surroundings, in her manner, and in her appearance, so is the Prince of Wales up-to-date. Marlborough house and Sandringham are fitted up with telephones and electric lights, in the most approved style. Should the prince survive his mother, his advent to the throne is likely to be marked by all sorts of innovations, which will have the effect of simplifying the present intricate manner of conducting the business of state.

In this respect he resembles his nephew, Emperor William II., of Germany, whose predilection for the telephone is a source of disgust to the various government officials at Berlin. There are instruments in his library and working room.

Although it may flatter the pride of the telephone people at Berlin to have the Emperor among the subscribers of the system, yet he gives them far more trouble than any other subscriber. For when he telephones to any of the government departments the operators at the central office are under the strictest orders to abstain from listening to the conversation.

VOL. XXIII. NEW YORK, JUNE 9, 1897. No. 475.

THE NATIONAL ELECTRIC LIGHT ASSOCIATION.

FEW of those who remember the storm and agitation that attended the last convention of the National Electric Light Association at Niagara Falls several years ago, would have believed it possible that the organization could survive such a disruptive performance. But the seasons have rolled by, each finding the association more useful, vigorous and influential, and it may be truthfully said that the body was never stronger than when it returns to the Falls to-day. In the interim the art has enormously advanced and the industry has grown with great rapidity; but the association has gained ground with equal strides, and takes its place high in the ranks of the representative national organizations devoted to the interests of great enterprise affecting the welfare of millions of people.

It is to be devoutly hoped that these encouraging conditions will continue to exist and that central station men and the managers also of isolated light and power plants will assist the association more and more as time goes by, with their personal membership and active co-operation. The association is built up and kept alive by individual effort, which in turn makes the combined action effective on public opinion and technical progress. So much is this true that we cannot do better than point with admiration to the work of President Nicholls and Secretary Porter. These two gentlemen have more than upheld the honorable traditions of the past. They have given the body an administration so energetic, harmonious, intelligent and broadly beneficial in its results that it will indeed be hard to surpass such a record. To President Nicholls the association is under the deepest obligations for his devotion to duty and his skillful guidance of its affairs, and his term of office will always stand out in bright relief, no matter how much good work precedes it, nor how earnestly his successors strive to leave a brilliant record also.

A CHART OF CENTRAL STATION LOSSES.

EVERY electrical engineer in charge of a central station knows that of the heat value of the coal thrown upon the boiler grate scarcely more than 1 per cent. appears as light in arc lamps, and but a small fraction of 1 per cent. appears as light in incandescent lamps. In this there is nothing startlingly new, but we think that there are not many central station engineers who could point out, with any great degree of accuracy, just where the losses between the coal pile and the lamp occur, and the amount of each such loss. With this in mind, we have believed that the industry as a whole would be benefitted by placing before engineers a chart which shows in a graphic manner a complete cycle of the energy as consumed in a simple central station. Such a chart, in several colors, forms the object of the special free supplement included in this week's Electrical Engineer, and the story which it tells is so plain as to require for itself no further elucidation on our part. It merely remains to point out that the chart represents the condition of affairs exhibited by the majority of stations now in operation, that is, a simple central station operated by high speed automatic engines driving countershaft. For the stations operated in a different manner, the intelligent engineer will readily be able to introduce, or eliminate, the factors brought into play by the different method of working. Taken as a whole, the chart forms a most impressive exhibit of the enormous wastefulness of our present methods of using fuel and steam and of generating and distributing current for lighting purposes. Though larger than the standard size of data sheets, which have become such a prominent and appreciated feature of The Electrical Engineer, the present chart will, we feel sure, find a prominent place among the handy data of every station engineer.

THE LATEST TYPES OF STANDARD ELECTRIC LIGHT AND POWER APPARATUS, 1897.

"OUR 1897 model" is the label which goes with every up-to-date bicycle, though the modification from last year's model is hardly distinguishable with the naked eye. We are glad to be able to say that such minute differences are not universally the characteristic of this year's models of standard electric light and power apparatus. Indeed, we know of scarcely any industry in which standard apparatus has undergone, and is still undergoing, such marked changes and genuine improvements as can be found in the materials of electrical engineering. These improvements can be traced not only in the improved forms and better designs of apparatus, but in the improved methods of manufacture, which make the older apparatus better adapted to its work than ever before. In order to show what the character of the present standard apparatus of to-day is, we have in this issue collated with the kind aid of the makers, the product of a large number of manufacturers; and we venture to say that the exhibit constitutes about as favorable a record of the art in America as could well be got into the space to which it is necessarily restricted. To those whose bent of mind lies in the direction of critical analysis, the various types of apparatus illustrated will furnish abundant food for the indulgence of their propensities, while for those who are contemplating a choice from a commercial standpoint the variety submitted will show how wide the field of choice is. Moreover, it is not unlikely that the record will prove very useful for future reference.

ELECTRIC TRACTION ON RAILWAYS.

CRITICS of the advances of trolley traction and its effect on steam railroads, do not fail to point out, very properly, that the trolley is exposed to some very severe limitations chiefly in having to stop so frequently, in running at lower rates of speed on a cheaper track and in operating on a lower basis of income. All this and much more is perfectly true, but it seems to us to fall short of the entire truth in failing to recognize the great probability that the limitations are on the part of steam, and that the advantages of greater range and wider flexibility lie with electricity. In other words, the trolley parallels, the long suburban extensions, the links between large cities and the newer rural electric roads have come in simply because steam has failed to give what is wanted. The reasons of failure are many but may be summed up broadly in the items of too great rigidity and expense. The trolley is giving service over an area and at a cost that steam cannot touch. But it is assumed that electricity is to stop short here, and to be restricted to the work of filling in the crannies and niches left vacant by steam. Is there any foundation for this? We venture to express the opinion that the present work on steam roads, done by trolley methods of frequent small units, is only a step. We see no reason why electricity should not cut both above and below this service. On the one hand it is likely to enable a man to go to a road at any time and run out a small vehicle over the track for his individual convenience; and on the other hand it has begun already to invade the domain of the big locomotive flying at express speed between points widely apart. The electric locomotive is already the subject of much attention but the "telpher" system lingers in the shade of undeserved neglect.

POSSIBILITIES OF CULM PILE AND COAL POWER TRANSMISSION.

THE potentialty of the culm or slack in the coal mines as a source of energy for electrical transmission has frequently been pointed out, and the cheapness of this material has led enthusiasts to predict for it a great future. Power transmission with coal as a source of energy has until recently resulted only in academic discussions, but if reports are to be believed a genuine project of this nature is now under way, and may within a short time be among the realities. The scheme involves the erection of a steam plant of no less than 20,000 horse power at Leavenworth, Kan., in the immediate vicinity of the coal mines in that town, which power is to be transmitted to Kansas City and to other points in the vicinity. Leavenworth, it may be added, lies in the center of a district having a population of two and one-half million, within a radius of forty miles. This, coupled with the fact that the railway rate per ton from Leavenworth to Kansas City, a distance of barely twenty-five miles, is $1.00 per ton, makes it possible it seems to convey the energy cheaper in the form of current than in the potential form of coal. As the first instance of this kind on record, this plant will of itself attract attention, but the engineering features in connection with it will make it particularly the subject of earnest inquiry among electrical engineers. It is contemplated, we understand, to build the steam plant in very large units, single engine units of ten thousand five hundred horse power being spoken of, and individual boilers of no less than 5,000 horse-power each. These figures overtop in magnitude any yet attempted in stationary engineering practice, and if they are carried out, as proposed, we may expect to see some novel results in steam practice.

We are glad to learn that the projectors of this new enterprise will work in harmony with the electric light and power distributing companies already established in Kansas City. Of course the success of this plan, if it should be carried out successfully, will again draw attention to the neglected culm pile. It is just as well, therefore, to reiterate the caution that the culm pile may or may not be a gold mine for power transmission purposes. It will simmer down to the simple question whether it is cheaper to burn the coal on the spot where it is mined, or haul it to the place where the energy is to be used. On the one side, the low price of the coal may be offset by the cost of maintenance of the transmission lines, while on the other must be included, of course, the freight charges for hauling coal. The enormously high freight rates at Kansas City may, and probably do, make it quite possible to transmit cheaper by electricity than by railway, but these conditions may not, and in the majority of cases probably will not, for a long time to come hold good as a general rule, nor are they permanent even there. But railway freight rates are likely to go higher, before they go lower. They seem to have touched bed rock.

NIAGARA

THE beauties and wonders of Niagara have been sung in verse and portrayed on canvas ever since the Falls became known to the white man. It has remained, however, for this utilitarian generation to look upon Niagara as something beyond a mere spectacle of nature, inspiring though that spectacle may be. As a source of power Niagara has now come to be the greatest example of the utilization of natural forces, and the meeting of the National Electric Light Association beside its banks is well calculated to bring the members of that body in closer touch with some of the most important work which has been accomplished in the whole history of electrical engineering. Within the last few years more than one manager of a station operated by steam has suddenly become aware that a copious water power within reachable distance was available for electric transmission, and there is now great development along that line. The trip to Niagara affords an excellent opportunity of examining the very high class of work thus far carried out at that spot. Under ordinary circumstances we should have felt inclined to devote some space to a description of the existing electrical work at Niagara, but we have been doing that persistently for some years past. The readers of our own articles on the subject in these pages, and of the numerous excellent contributions from Mr. Orrin E. Dunlap, our Niagara correspondent, have learned all that is worth knowing, except as to the results of actual operations, and at the present writing there is literally nothing to add, except by way of wearisome repetition. The contents of this large current issue of The Engineer will therefore be conspicuous for the absence of familiar news about Niagara, but, we trust, of such an interesting nature as to justify us fully in giving Niagara a well-earned rest.

MOTORS IN FACTORIES.

ONE hears funny things at conventions. For example, at the recent meeting of the American Society of Mechanical Engineers at Hartford, in the discussion of the use of motors, a sapient Mr. Rockwood said he knew of several concerns that had adopted electric driving unwisely, bankruptcy following! He thought that the least useful place for a motor was in the machine shop! We are reminded of a street railway convention we participated in some years ago when one of the delegates grumbled bitterly about the devotion of any time to this "new fangled thing 'lectricity." He had come to the convention to find out how to shoe his horses and dispose of their manure, and he had neither money nor leisure to waste on the new craze. The trouble with that street railway hostler and with Mr. Rockwood, the latest mouthpiece of prejudice, is their evident inability to distinguish between mere crazes and deep seated social and industrial revolutions.

MR. TESLA announces in the Sunday "Sun" that by his well known system of transmitting intelligence by means of electrical "resonance" between points widely apart, without any connecting wires, he has lately been able to signal twenty miles. This is a splendid achievement. Mr. Tesla confesses that the system is still liable to break down in bad weather, but such results will doubtless encourage him to persevere until the distance is many times greater and the method is quite independent of disturbing atmospheric or terrestrial effects.

THE present issue of The Electrical Engineer consists of no fewer than 136 pages, and a four-page special supplement. That this journal in these dull times should be able to give such noteworthy evidence of progress and prosperity is a matter of pride to the management, and, it is believed, will be a source of gratification to the friends of the paper.

OPENING OF THE NIAGARA N. E. L. A. CONVENTION.

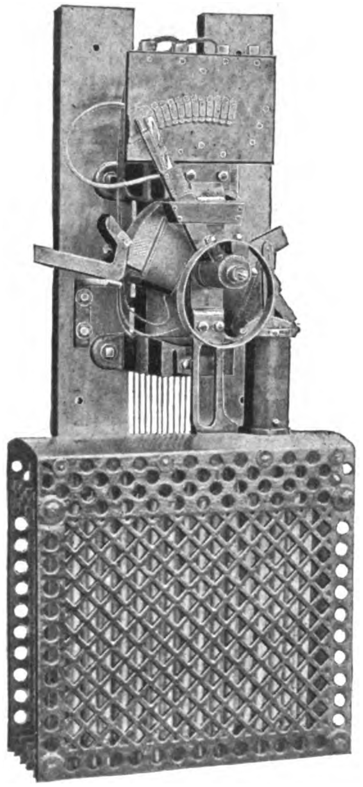
Special Dispatch to The Electrical Engineer.

Niagara Falls, N. Y., June 8.—Convention opened this morning with an attendance of over three hundred and a great many more are expected to-day. Frederic Nicholls, J. I. Ayer, E. A. Armstrong, C. R. Huntley, A. M. Young and Samuel Insull are among those present. Several of the delegates are accompanied by ladies. A noteworthy feature is the large number of city and state officials attending, charged with the regulation of electrical service. There is a good muster of central station men, including delegates from as far away as California and Louisiana. The special trains all made excellent runs. The weather is most unfavorable, but promises to clear. If the delegates stick to business, there is every indication of an unusually hard-working and useful convention. The papers are in the secretary's hands almost without exception, and the special committees have interesting reports to file. Universal regret is expressed at the unexpected news of the resignation of Secretary George F. Porter, whose intention is to enter commercial life again. Convention rumor points to Mr. A. M. Young, of Waterbury, Conn., for next president. T. C. M.

CARD AUTOMATIC MOTOR STARTER.

FOR some months past the Card Electric Company, of Mansfield, O., have been experimenting and making careful tests with various forms of automatic starters or controllers for elevator motors, with the result that we illustrate in the accompanying cut a motor starter, containing features of construction that would seem to make it a very effective and durable apparatus for the hard duty of operating the common every-day kind of freight or passenger elevator.

The rheostat and operating parts of the starter are mounted on a neatly finished wood frame, and all the connections between the rheostat and cut-out are made before leaving the factory. The construction of the automatic rheostat cut-out is simple in the extreme and the magnetic force to operate it is very strong, far in excess of any possible requirements. This part of the apparatus has received careful attention since the practical success of the starter depends almost entirely on the reliability of the swinging arm to divert current properly from the rheostat when the circuit is closed. The electromagnet used for this purpose is a powerful one and has a swinging armature wound and energized by the same current which creates a powerful torque, and this torque is so controlled by the connecting mechanism that a constant steady pull is maintained throughout the full movement of the arm. The speed of the cut-out can be made anything desired. All the bearings and moving parts are mounted on rollers or balls, dispensing entirely with the necessity of ever oiling them, and eliminating any possible danger of sticking because of accumulated dirt or friction.



Card Automatic Motor Starter.

The dash-pot for controlling the "on" movement of the swinging arm has some novel features to insure regularity and constant speed, and the relase valve in it is so proportioned and constructed that an almost instantaneous throw of the swinging arm to the "off" position is effected whenever the current is interrupted.

The rheostat used with this starter is of the well known Card type, made up of iron wire coils, mounted on iron frames, put together in a substantial manner with free ventilation on all sides. Perforated iron plates protect the front and back. The reversing switch, which is a part of the Card company's elevator equipment, is of the quick throw type and has carbon break tips on all the contact blades. A combination of this starter and switch with any one of the several types of motors built by the Card Company makes a very substantial equipment for either freight or passenger elevators.

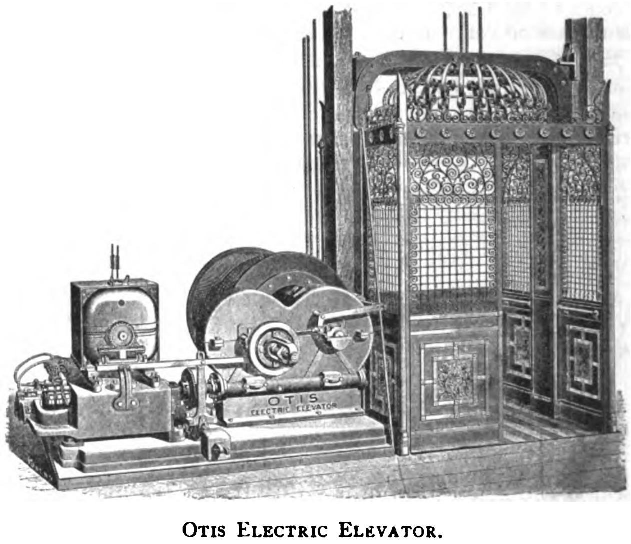
NIAGARA FALLS POWER CO.

At the annual meeting of the Niagara Falls Power Company, held at Niagara Falls, N. Y., on June 1, officers and directors were elected. They were the same as last year. The capital stock of the Power Company was increased from $3,000,000 to $3,500,000. The contract for the building of the addition to the power house, and for the structural steel work for the wheel-pit, will be awarded at a meeting to be held in New York shortly by the directors of the Power Company.

THE OTIS ELECTRIC ELEVATORS.

THE grand stairs in office buildings, in many of our luxurious and private residences have in these days of mechanical locomotion become largely traditional ornaments, having ceased to be used as a means of communication between the various floors of these buildings. The feeling of annoyance and fatigue incident to climbing in buildings has become so universal that even the most conservative insist on the luxury of the modern elevator. The opportunity offered by the many central stations for supply of power and light for private residences made an elevator service for these places possible where any member or guest of a household could operate the elevator with absolute safety.

Since 1884 Messrs. Otis Brothers & Co. have been the pioneers in introducing electrical devices, which as far as human foresight goes must insure absolute immunity from accidents. The principle on which these devices are constructed is that any interference with the control and operation of the elevator by any other person except the one having possession of the car must be made impossible. It must also be impossible to start the car from any other place, or even from the car itself, until all the entrance doors are closed and until the occupant has left the car and closed the entrance door after going out.



Otis Electric Elevator.

Outside of these special safety devices for enabling the operation of the elevator by any person, or without a permanent operator, the apparatus is provided with the best regular safety devices which have made elevator travel safer than any other mode of conveyance. A stop-motion is provided to stop the car automatically at the upper and lower landing, and in case the car stops itself in its down-motion, by its safety device or by an obstruction. Any excess over the safe speed is prevented by the automatic governor safety, and a toggle safety brake.

The motor is of the Eickemeyer iron clad type, with the Eickemeyer armature winding and limit switch. This limit switch automatically insures a start with an amount of resistance in the armature circuit to admit no more than the maximum working current, when running with maximum load. The field is arranged to start with a number of series coils in combination with the shunt coils, but at normal speed the series coils are cut out automatically, and the speed is controlled by the pure shunt field. These elevator motors will lower the load without a brake. The combined electrical and mechanical compression brake is used only to stop the car and keep it in place at the landings.

The electrical and mechanical details of construction are complete and the best in every respect, and produce the highest economy in the consumption of power and in the cost of maintenance of the whole apparatus. This successful result is greatly due to the careful distribution of surface pressure by means of the duplicate worm gearing, and to the utmost limitation of the starting current.

NORTHERN ELEC. MFG. CO.'S SPEED REDUCING DEVICE FOR ELECTRIC MOTOR DRIVE.

The Northern Electrical Manufacturing Company, Madison, Wis., are putting upon the market a novel arrangement by which they use a standard motor in their various sizes, at the same time imparting to driven machines any required slow speed. This is accomplished by the use of their patented invertible bonnet and back gear device. Absolutely no outboard bearings are used, and the construction is such that there is no possibility of the mechanism getting out of alignment. All the bearings are self-oiling, and the entire mechanism may be run without using any floor space. All of the Northern motors and their various equipments are so built as to run inverted, if necessary, and attached to the ceiling, or half inverted and fastened to side wall or post without so much as removing one bolt. All their standard motors are also furnished with tight fitting portable covers for keeping out any dripping from floors above, or dust and dirt. These are immediately attachable to their regular standard bonnets, so that they may be used or not, at the will of the operator. These motors are especially well adapted to factories where there is much dirt and moisture and to mines and foundries.

THE C & C ELECTRIC CO. IN CHICAGO.

The C & C Electric Company have recently concluded arrangements with Messrs. Sargent and Lundy, of 13 and 15 Monadnock Block, Chicago, Ill., whereby this firm on and after August 1st will act as their selling agents for Chicago and the Western States. Early intimation of this important deal was given some time ago in The Electrical Engineer. During the interim Mr. F. D. Sweeten, who has long been the manager of The C & C Company's Philadelphia office, will look after the company's interests in the territory above mentioned.

The company's Western office is for the present at 934 Monadnock Building, where Mr. Sweeter can be found and where business will be transacted until the change alluded to above shall go into effect. Mr. Martin J. Insull, of Messrs. Sargent & Lundy, will have special charge of the interests of The C & C Electric Company.

NEW AMERICAN TURBINES AT GREAT FALLS, MONTANA.

THE Dayton Globe Iron Works Company, of Dayton, Ohio, have recently finished the construction and erection for the Boston and Montana Consolidated Copper and Silver Mining Company, of Great Falls, Mont., of what is probably the largest and most powerful pair of horizontal turbines, for the head of water under which they will operate, that have ever been built.

These turbines are of the New American pattern of the latest design, 57 inches in diameter, and under the head of 50 feet will develop 3,945 horse power. The turbines are placed on a cast iron draft chest and discharge centrally through a draft tube 10 feet in diameter, and are incased in an iron flume 14 feet 4 inches in diameter, 32 feet 6 inches long, made of ½-inch tank steel, with cast iron heads, and the flume is mounted on two pairs of double I-beams, 20 inches deep, 38 feet long.

The shaft in the wheels is 10 inches in diameter, 42 feet 2 inches long, made in two sections, and its weight is over five tons. The clamp coupling which connects these two sections of shafting in the center of the draft chest weighs considerably more than one ton. There are stands, weighing 8,000 pounds each, outside of flume at each end, which carry the journal boxes for this shaft. The two turbines, with their complete outfits, weigh approximately 250,000 pounds, and in their design and construction reflect great credit upon the engineering skill of the Dayton Globe Iron Works Company, and are also an excellent example of their ability to construct this class of machinery on the largest scale.

These turbines operate two Westinghouse electric generators, one coupled directly to each end of the shaft, which runs from 144 to 160 revolutions per minute, and are used for electrolytic refining. The varying revolutions are required in order to increase or diminish the current as conditions may require.

The power of these wheels is also utilized for driving an arc light dynamo and the two 50-horse-power exciters for the large generators, the power being transmitted from wheel shaft to dynamo by means of a 20-inch double leather belt, and there still remains a surplus power in the wheels, which is not being utilized at present.

It is further estimated that if a pair of these 57-inch New American Turbines of this design and capacity were placed in operation on the new water power at Niagara Falls under 140 feet head they would develop 18,494 horse power, and would require a shaft 15 inches in diameter to safely transmit the power, estimating the power to be taken off at each end of the shaft, as is the case at Great Falls, Mont.

Before shipping these wheels to Great Falls, the builders had them tested at the testing flume of the Holyoke Water Power Company, Holyoke, Mass., and both the right hand and left hand turbine showed an average efficiency from three-quarters to whole gate, inclusive, of 81¼ per cent., which is a remarkable performance, particularly in view of the fact that these turbines were the first ones ever made of that diameter by the Dayton Globe Iron Works Company. These wheels were sold on a guarantee that they would show an average efficiency of 80 per cent. from three-quarters to whole gate and would develop 2,800 horse power under 40 feet head, and they exceeded the guarantee both in horse power and efficiency. These wheels are shown very faithfully in the advertisement on pages xxxiv and xxxv.

IMPULSE WATER WHEEL EXPERIMENTS.

BY E. A. HITCHCOCK.

THE ever-present genius of mankind, to utilize as he may need, the force of nature, has led to a development, during comparatively recent years, of that class of water motors known as the tangential or impulse wheel, designed especially for the utilization of water powers under high heads, where the conditions are such that the use of gravity and pressure wheels, that is, overshot, breast wheels, turbines, etc., would be mechanically impossible on account of the excessive heads, reaching in some instances 2,100 feet.

On the other hand, the impulse wheel can be used, for small powers, to advantage on heads as low as 50 feet on account of their greater simplicity, ease of repair, lubrication and reduced first cost, at the same time showing a high efficiency.

The theoretical action of the wheel lies simply in a jet of water impinging on buckets of such a shape that the direction of the stream will be completely reversed and the velocity of jet on leaving the wheel equal to zero, all the energy of the stream being imparted to the wheel. In the mounted impulse wheel, there may be considered, three sources of loss, the nozzle not being considered a part.

1. Loss due to non-reversal of stream.
2. Loss due to mechanical action, interference of particles and friction of water on the surface of the buckets.
3. Loss due to friction of the wheel in its bearings, which can be determined graphically as follows: Make A A', Fig. 3, equal to the diameter of the pitch line of the buckets and N N' the diameter of the shaft in its bearings. Now, D C E is the angle of action of the jet on the buckets and F F' the direction of that jet intersecting the pitch line at the point of bisection of the angle D C E. Make C W equal to the weight of the wheel, shaft, etc., and A' B to the pressure of the absorbing brake, then will G W B be the position and direction of the resultant of these two parallel forces. From the intersection of F F' and G W B, lay off E W B equal to C W + A' B and draw the diagonal E R passing through the center of the shaft. Then E R will be the resulting pressure on the bearings in the case of no friction and W B R will represent the energy required on the part of the jet in the case of no friction. For the case of friction make ϕ, whose tangent is the coefficient of friction, equal to the angle of repose. From the intersection of C H with the circumference of the shaft, and through E, draw E R'. This will be the resulting pressure with friction and W B R' will be the energy required on the part of the jet, therefore $100-\frac{W B R}{W B R'}$, will be the per cent. of loss, due to friction of bearings.

Although from the above relations, it is noted that high efficiency depends principally upon such a shape of bucket as to give as near as possible a complete reversal of stream and a periphery velocity of one-half that of the jet, yet it has been found by a series of experiments, carried on by Messrs. Donham, Frayer and Cilly in the hydraulic laboratory of the Ohio State University, that the maximum efficiency for a certain width of bucket, depends upon the size of tne jet and also the position of the jet in the plane of the pitch line.

The wheel used in the experiments is known as the Cascade, manufactured by James Leffel & Co., of Springfield, O., and was 25⅞ inches in diameter and had 28 buckets, located alternately on each side of a sharp cutting ridge, which serves to divide the jet before reaching the buckets. A 10 x 7 x 10 inch duplex pump was used for furnishing the necessary water supply, pumping from a water bay of 2,500 gallons capacity, into a stand pipe or air chamber 24 inches in diameter by 24 feet high, to which was connected by a 5-inch pipe, the Cascade wheel tested. The wheel was located over another water bay of the same capacity as the former, a weir connecting the two. Calibrations of the nozzles used indicated the amount of water discharged, and the Prony brake the amount of work developed.

Running the Cascade wheel under various speeds at a constant velocity of jet, the results, from which the curve, Fig. 2, is constructed, are as follows:

Diameter of nozzle 1 inch: Length of brake arm 3.183 feet.

Number of trial—	1	2	3	4
Velocity of jet. Ft. per sec...	102.4	101.7	102.3	102.1
Wt. of water discharged per minute	2086	2075	2085	2078
Energy of jet. Ft. lbs.	339600	333219	338750	336278
Net load on brake, lbs.	25	30	35	40
Revolutions per minute	542.3	482.8	447	377.4
Energy developed. Ft. lbs...	271150	289680	312900	301920
Efficiency of wheel	79.84	86.93	92.36	89.78

Results for the best efficiencies of the same wheel with different diameters of nozzles, are as follows, and curve of Fig. 1 constructed from the same.

Size of nozzle.	⅞"	1"	1¼"
Velocity of jet. Ft. per sec...........	99	102.3	103.5
Weight of water discharged per min..	1548	2085	3340
Energy of jet. Ft. lbs................	235518	338750	555524
Net load on brake....................	20	35	55
Revolutions per minute	483.9	447	445.2
Energy developed. Ft. lbs............	193560	31290	489720
Efficiency of wheel..................	81.76	92.36	88.15

Taking the highest efficiency as found by trial, that is, the ratio of the work given ou at the pulley to that stored in the jet after leaving the nozzle, the three losses would be:

First, that due to non-reversal of jet. With the wheel in question, the angle of deviation from the original direction of the jet, is 163 degs. Therefore $E = \frac{1}{2}(1 - \cos 163^\circ) = 97.81$ per cent.; or 2.285 per cent. loss.

Second, that due to the friction of the bearings. Making an application to Fig. 3, trial No. 4, where the diameter of the shaft is 1¾ inches, diameter of the pitch circle 23¾ inches, weight of wheel 200 lbs., the net load on the brake 35 lbs., and assuming the tangent of the angle of repose to be .01, the coefficient of friction, $100 \frac{W B R}{W B R^1}$, (Fig. 3) equals .26 per cent., giving a total loss due to non-reversal of stream and the friction of the bearings of 2.545 per cent., which would give for the second loss, that due to the friction of the water on the buckets, mechanical action of particles, etc., for the trial in question, 100 — 92.36 — 2.545 = 5.095 per cent, which will also include the energy of the jet lost, if any, due to the departing velocity being greater than zero. Therefore we have, loss (1), 2.285 per cent.; loss (2), 5.095 per cent.; (3), .26 per cent. Efficiency of wheel, 92.36.

NEWS AND NOTES.

METHOD OF RENDERING FUSES RELIABLE.

BY LOUIS W. DOWNES AND WILLIAM C. WOODWARD.

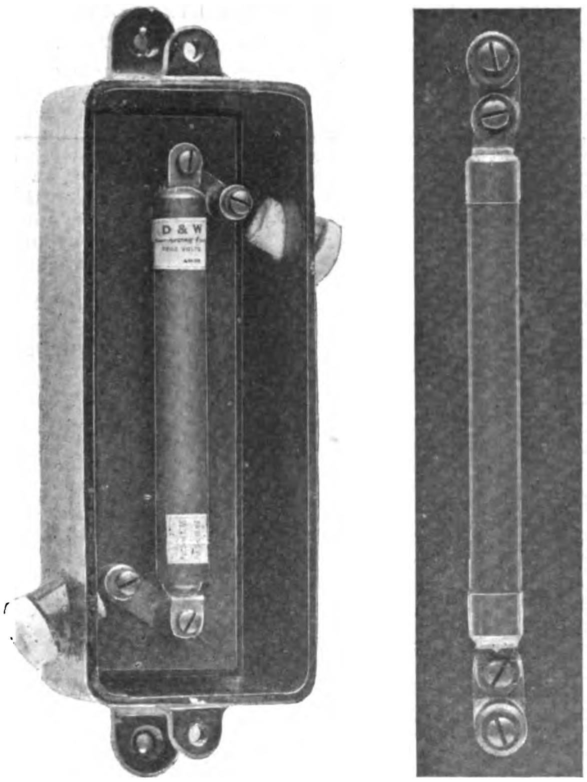
CONSIDERABLE interest has been manifested during the past year or two on the subject of fuses, and so much has been written and said that one might readily believe tne subject had been thoroughly exhausted, with the result, judging by the papers so far presented, that fuses as protective devices were almost universely condemned. Believing, however, that the defects shown were due more to the manner in which the fuses were used and the poor design of the apparatus, we determined to investigate the matter, and the results of our tests, extending over a period of more than two years are now made public.

The so-called inherent defects of the ordinary fuse are, as is well known, an apparent variable melting point, and the liability of fierce and destructive arcing at the moment of rupture under heavy load or short circuit.

Let us carefully examine the conditions and see if the fault is not more in the way in which it is used than in the fuse itself. A variable melting point may result from several causes, viz., location, exposure to draught, contact with adjacent bodies, variation in length or irregularity of cross section; also size and composition of terminals. The first three are, however, the most frequent causes of uncertainty and yet have had the least attention in the way of remedy. A fuse exposed to a strong draught will naturally carry a larger current without melting, than one so placed or arranged as to be free from draught; again a fuse left in contact with a body a better heat conductor than air, will act in the same manner, and it is astonishing how great an effect the slightest contact will have. We have observed instances where a contact not extending more than one-eighth of an inch in a length of 2½ inches with so poor a heat conductor as paper, would change the time of blowing for a given current about 30 per cent. A sensitive device is demanded and yet complaint is raised when it demonstrates its sensitiveness.

The fault of arcing under short circuit is a much more serious trouble, when we consider high potential circuits, but with low potential main line cut-out and branch blocks we believe it to be due largely to the imperfection of the design. The distances between terminals are often ridiculously short, often less than the length of the fuse, which has to be bent to get it in place. No attention has been given to the amount of energy represented by the severe discharge of a short circuit or sudden heavy overload; convenience and appearance apparently having determined the proportions of the so-called safety device.

If we consider that an arc is the result of the formation of a stratum of conducting vapor, due to the volatilization of the fuse metal (and that, once formed, it tends to feed itself by the destruction of the terminals), the matter of overcoming it is not so difficult as might at first appear. To prevent its continuance we have naturally to break up or interrupt this vapor, as we would a metallic circuit, and then dissipate or remove it. If we first enclose our fuse within an insulating tube and then surround it by a mass of suitable, finely divided, material, we have nearly solved the problem of producing a reliable fuse, for, in the first place it is protected from air currents, it is rigidly supported and cannot change its position, and, finally, the multitude of minute paths provided by the space between the filling, disintegrates or divides any vapor formed upon the rupture of the circuit, cooling and allowing it to escape so that an arc cannot be maintained even under the most exacting conditions.



Types of the D & W Non-Arcing Fuse.

A new difficulty, however, here presents itself, due to the fact that the fuse is in contact with another body of variable heat conductivity, throughout its length. If the surrounding material be cold the heat due to the passage of any given current is at start conducted away very rapidly, with the result that the melting point of the fuse is carried far beyond its melting point in air for a given time value. For example, a certain ten ampere fuse 3½ inches long will blow in air at 15.8 amperes in approximately 32 seconds under favorable conditions. The same fuse enclosed as described will carry 50 amperes for over a minute, if cold at the start, or it will carry 30 amperes for thirty minutes. There is what might be called an absorption of heat by the surrounding mass which is gradually raised to a high temperature, the rate of absorption becoming less and less, so that finally the melting point is reached.

This effect would of course be disastrous in practice since the melting point would vary according to the length of time the fuse was in circuit, that is to say, would gradually decrease. Our first effort to overcome this defect was to increase the radiating surface, but this was ineffective, due to the fact that both the tube and the filling were too imperfect conductors of heat to be influenced by any material increase of surface. The method then adopted and found to answer all requirements, was to preserve an air space at the center of the tube within the filling.

Small paper drums or closed cylinders are slid over the fuse and secured at the center. The air confined in this way, being a poor conductor of the heat, prevents its too rapid absorption by the surrounding material at that point, the result being that the melting point is always the same; that is to say, with any given fuse, the melting point always occurs at the same time for any calculated current excess.

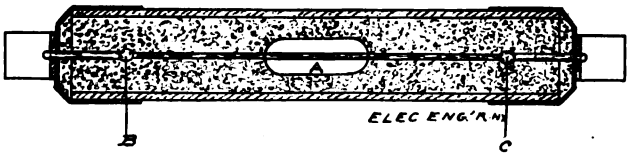
Reference to the accompanying illustration will show the arrangement we have found most satisfactory for the purpose. The fuse wire or link is soldered to copper terminals at points B and C, the air drum A having first been threaded over the fuse and fixed in place by cement. It is then placed within the tube and the filling packed tightly about it, the ends being closed by suitable brass caps in which are cut ventilating slots to allow the vapor produced in short circuit to escape.

By this method it will be found that all the defects of the fuse are overcome. In the first place, its length becomes a fixed value, as are also the dimensions of the terminals. It is rigidly supported in a fixed position which cannot be changed by careless workmen; its insulating covering and the fixed volume of air at the center prevent variation of the melting point, which will be found accurate as regards time and current value to within a small percentage; and finally upon short circuit there is no discharge, flame or noise of any description, and an arc will not be maintained. We have frequently held a fuse in the hand and connected the terminals directly across the mains of a 400-kilowatt, 2,000-volt alternator and could only determine that the fuse had blown by feeling a throb in the tube similar to a pulse beat!

We have enclosed these fuses within an air-tight box connected with a U gauge and upon a short circuit discharge, the liquid would slowly rise, showing but 1.28 ounces per square inch increase in pressure developed, the internal dimensions of the box being but 7 x 2 x 3 inches.

The question of the composition of the filling in the tube was soon found to be an important one. Starting with coarsely granulated marble and with sand it was found that in fuses above three or four amperes capacity there was on short circuit, heat enough developed to melt the silica in the filling, and this combining with the metal of the fuse, formed a peculiar species of slag or glass. Under certain conditions with fuses of high capacity this slag would completely stop the ends of the tube and prevent the escape or dissipation of the vapor, with the result that an arc of the most destructive character would be maintained, sometimes burning its way through the sides of the tube near the center, at times bursting it open with great violence. When the capacity of the tube is great as compared with the amount of metal in the fuse a short circuit would result in the formation of an elongated cylinder of the slag which was readily removable from the case. The material forming the cylinder produced in this way, was sometimes so hard that it would readily cut glass and was probably similar to carborundum in its nature.

A filling was finally discovered which answered all the requirements, as there is now no melting or combination between it and the metal, examination of the filling after short circuit only showing the mass to be slightly blackened at the center with rarely any particles of the metal left, all of it apparently being vaporized. Upon this principle we have constructed fuses up to 100 ampere capacity (by this we mean a fuse that will carry that amount of current indefinitely) and short circuited them on a 500-volt power circuit without flash or discharge of any nature.



The D & W Safety Fuse.

We have also constructed fuses for the 1,000 and 2,000-volt circuits (alternating) with perfect success, although we are limited here as to ampere capacity in our tests, for, although the machines supplying the circuits are of 400-kilowatt capacity, we find that above 20 amperes a short circuit reacts on the fields of the machinery, bringing the voltage down almost instantaneously, so that the fuse simply blows as if from overload.

While this may seem to be a very small fuse, it must be remembered that the rating is for load amperes, that is to say, the current that it will carry indefinitely. The blowing current is consequently much in excess of this, and on short circuit it would rise to a very high value, being controlled only by the resistance and self-induction of the circuit, which are both low. The fact that the field of the alternator is killed shows that the amount of current appearing in the fuse must be something in excess of the output of the machine (200 amperes) at the instant of closing the switch.

We have employed these fuses on 2,000 volt alternating circuits supplying motors of large capacity and on several occasions our fuses have operated on these, with fairly heavy lag currents, without flash or noise. We have also tried them on lines possessing high self-induction with equally good results, and these two conditions would be about the most severe that could be imposed. We have been unable as yet to make any absolute determination of the total energy dissipated in this way within the tube, but are experimenting on a method which we believe will give us this value very accurately.

The question of fuse rating is one that we believe has not been made sufficiently clear to the average construction man, as we frequently hear them speak of a 10 or 25-ampere fuse as one that will melt at that current value, and it is with difficulty that they can be made to understand that without the time factor such a rating means absolutely nothing. There is no definite standard at the present time as far as we can determine, the various manufacturers using different ratings which necessarily leads to a great deal of uncertainty and confusion. Our own tests indicate that the correct method of rating should be by the maximum current that the fuse will carry indefinitely, with the surrounding temperature at 70 to 75 degs. Fahr., and such a method we believe to be the most desirable from both a practical and scientific standpoint. By this method we know definitely from the marking on the fuse just what we have and can allow any necessary overload factor according to the service.

A non-arcing fuse rated in this way will carry a 10 per cent. overload for a considerable period while at above 30 per cent. the time factor is reduced to less than a minute, there being a sharp turn in the curve at that point. This feature gives to the fuse an elasticity which is very desirable, particularly on motor supply circuits, since it admits of slight overloads for some little time, but as soon as this becomes in any way excessive, the time value is so materially reduced that danger to the apparatus is avoided.

The use of fuses of proper design on motor circuits is certainly a more reliable safeguard against continued overload than any mechanical circuit breaker, for in the latter device the current may be long continued at a dangerous point without any action of the automatic breaker, while in the case of the fuse the time factor is a sure safeguard against long continued currents of abnormal capacity.

As an illustration of the above, assume a 10-horse-power motor on a 500-volt current, the normal current at full rated load would be about 17 amperes, but at moment of starting if full load is on, the current may rise to 30 amperes or more for an instant. If the current is controlled by an automatic breaker the "knocking off" point must be set above 30 amperes, or else the breaker will come out when the motor is started. If by any reason the motor is overloaded for any length of time or any fault develops which increases the current strength, say, to 20 or 30 amperes, the breaker is no protection and the motor would burn out before the circuit would open. On the other hand, if a 20-ampere fuse of proper design was used as a protecting device the momentary current increase would not open the circuit, but if long continued the circuit would be interrupted before the amount of current was sufficient to endanger the safety of the motor. We are by no means alone in the stand we have taken, that the fuse when properly designed is the best protection on circuits of constant potential.

THE LYNN INCANDESCENT LAMP CO. AND ITS WORK.

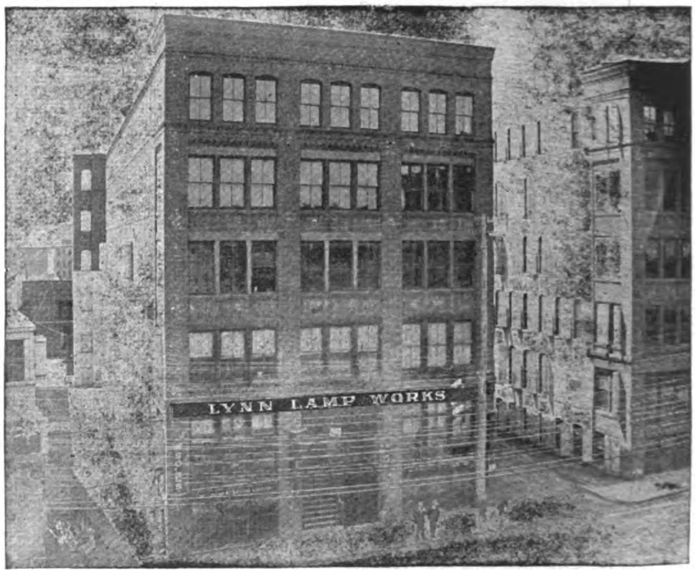
It is with interest that we watch the growth of electrical industries that in spite of the continued slow turning of the wheels of business of the rest of the world, force themselves forward in a compartively short space of time and make themselves necessary factors in the principal branches of electrical practice. The promoters of such enterprises shrewdly take advantage of existing conditions, and assist the station manager to reduce his running expenses and make the most of what he has.

A typical example of this class is the Lynn Incandescent Lamp Company, with their renewal system. While they make a specialty of renewing burned-out lamps, they turn into good lamps or cash, everything in connection with a lamp that is usually thrown away. They began operations about a year ago, and that they struck a keynote, is evidenced by the rapid growth and popularity of their business, soon outgrowing their birthplace. Their working floors are well lighted rooms, 175 feet in length, and covering 10,000 feet each. This enables them to move the work with greatest possible economy.

Upon receiving a lot of lamps to renew at their receiving department, they are first carefully counted, and report sent to the office of the number, kind, etc. This report is checked with the correspondence, and an order placed at once upon the shipping department, to ship this party a certain number of lamps, of such voltage, base, efficiency, etc., it being part of their design not to require a customer to wait for their lamps to go through the factory, but to make him a shipment at once of lamps of the same voltage and base, or whatever he desires, in return.

The first operation the lamps go through is to test them for vacuum, and see if there are any which have burned out on account of the bulb's leaking. Quite a few of some makes of lamps are found to be full of air, having evidently leaked. These are rejected at once and repaired separately or broken up. This feature alone they claim places the total life of a given number of their lamps beyond that of the same number of new lamps.

Next, the bulbs are sorted into their several sizes in order to be fitted with a filament that would look well in the bulb, the coil type being used in the short bulbs, and the loop type in the long bulbs. After this the tips of the lamps are removed with a file, and the opening enlarged to about the diameter of a lead pencil. Through this opening the old filament is removed, and the new one inserted. It is then cemented into position by a cement which is a good conductor, and will stand a high temperature. The invention of this paste was the first step toward rendering possible the business of repairing a lamp, and is due to the company's manager.



The Lynn Incandescent Lamp Works.

A peculiarity of the lamp which claims one's attention at this point, is the manufacture of the filament itself, which is different from anything used by other companies. The filament has a very high specific resistance, and requires a very thick surface of flashed carbon. This flashing process is carried on in chambers, having a vacuum of 30 inches. This is obtained by a special pump of the company's own design. The company has found that the quality of this flashed surface depends to a great extent on the degree of vacuum. The higher the vacuum, the more homogeneous and smoother the resulting carbon. The company also make it a point to have a large percentage of the filament of this nature.

The next operation after mounting the filament, is to clean the bulb of the black deposit from previous use. This is accomplished by revolving the lamp in a suitable holder in large gas burners, which effectually remove every trace of blackening from the lamps. Immediately following this operation, a small glass tube is fused to the opening made in the bulb through which the air is drawn by a system of pumps.

As noted above, this company does not use a mercury pump, but in its place a small mechanical pump of their own design. This pump is a small machine, and is eminently suited for the exhaustion of X-ray tubes, and general laboratory use. The pump has not been put on the market, though the matter is under serious consideration.

The lamps are exhausted one at a time and the entire attention of the operator is given to one lamp until it is finished.

When the lamp is exhausted to the satisfaction of the operator, a small blow pipe flame is directed upon the tube and melted into a point—a perfect counterpart of the tip of the original lamp. The lamp is now ready to be measured on the photometer for candle power and voltage. The lamps are sorted, all lamps of one voltage and efficiency being placed together, and after going through the usual tests, are washed, labelled and wrapped ready for shipment or stock.

Mr. E. F. Dwyer, the manager, states that for a low volt lamp, 3.4 watts per candle is a very popular efficiency; for high volt lamps, 3.2 and 3½, 3½-watt lamps even satisfying those people who desire a very long-lived lamp. For railway work they make a 4-watt lamp with a very short filament, which does not require an anchor. Mr. Dwyer is very confident that he will do a very large business the coming year.

MARRIED

PSCHORR-BERGMANN.

A fashionable wedding on Washington Heights, New York City, June 2, was that of Miss Louise Helen Bergmann to Josef Pschorr, of Munich, Germany, which occurred at the home of the bride's parents, Mr. and Mrs. Sigmund Bergmann of One Hundred and Forty-sixth street and St. Nicholas avenue. The interior of the beautiful house was transformed for the wedding into a veritable flower garden. The ceremony was performed by Dr. Halfmann of the Lexington avenue Lutheran Church, the couple standing in a bower of roses. The bride wore a gown of white satin, trimmed with point lace, and a tulle veil, caught with a sunburst of diamonds, a gift of the groom. She was attended by her sister, Miss D. Bergmann, in pink silk. The bridesmaids, Miss Charlotte Schafer and Miss Adele Friedman, wore nile green. Dr. Robert Pschorr, of Berlin, was best man, and the ushers were Dr. R. Loreck, Mr. Charles Foster, and Mr. Charles W. Ohmeis. A great many handsome presents were given, and the gathering of friends was very large, among them being noticed Mr. S. Insull, who as an old friend had come all the way from Chicago to attend the ceremony. The father of the bride is the well known electrical inventor and manufacturer, who has large interests on both sides of the Atlantic. The couple left during the evening on a brief wedding tour, and will sail for Germany in about two weeks, to make their home in Munich.

Among the guests may be mentioned T. A. Edison and wife, E. H. Johnson and wife, Chas. P. Geddes and wife, Fred Noll and wife, Eugene Lewis and wife, Philip H. Klein and wife, W. E. Gilmore and wife, John W. Lieb, Jr., and wife, and Messrs. Jos. Williams and W. E. Mandelick.

MAHER-GILROY.

All Saints' Church, One Hundred and Twenty-ninth street and Madison avenue, New York City, presented a brilliant scene at noon June 2, when Miss Frances E. Gilroy, daughter of ex-Mayor and Mrs. Thomas F. Gilroy, became the bride of Mr. Edward A. Maher, Jr., son of ex-Mayor of Albany Edward A. Maher, now a resident of Harlem. The ceremony was performed by the Rev. John J. Keoghan, pastor of the Church of St. Thomas the Apostle, assisted by the Rev. J. Power, pastor of All Saints'.

Following the ceremony was a reception at the residence of the bride's parents, 7 West One Hundred and Twenty-first street. The young couple received many beautiful presents, including a silver service of 270 pieces from the employés of the North River Electric Light Company, of which the bridegroom is treasurer.

EDWARDS—STAFFORD.

The wedding of Miss Ida Maud Stafford and Robert Edwards was celebrated on June 2 in the Calvary Methodist Episcopal Church, Seventh avenue and 129th street, New York City. The Rev. Dr. McChesney, the pastor, performed the ceremony at 8 o'clock. The bride's sister, Miss Bessie Stafford, attended her as maid of honor. A reception, with supper, followed the church ceremony, at the home of the bride's parents, Mr. and Mrs. Harlow H. Stafford, 225 West 126th street. The bridegroom is an active member of the New York electrical manufacturing firm of Edwards & Co., in which he is associated with his father.

OBITUARY

CHARLES LEE CROWLEY.

Many of our readers will be pained to learn of the death of Charles Lee Crowley, an able young electrician, at his home at Hamilton, Ohio, on the 28th of May, in his thirty-fourth year. He was first connected with an electrical firm in Cincinnati when he showed rare ability, and later on became associated with the Denver (Col.) Traction Company, where he remained till 1895. He left Denver in that year to accept a position as engineer for the firm of John T. McRoy, the conduit manufacturer. He was singularly popular. He was a man of extensive travel, and his mind was stored with the fruits of exhaustive reading. In Mr. McRoy's service he visited the principal cities of the country, and made electrical friends wherever he went. The Hamilton papers on the occasion of his death spoke in the highest terms of the many good qualities that Mr. Crowley possessed.

PERSONAL

DR. W. E. GEYER, of the Stevens Institute of Technology, lectured before the department of physics of the Brooklyn Institute on May 25 on the subject of Self-Induction.

MR. CHARLES E. PATTISON, for the past six years in charge of the construction and operating of the stations of the Edison Electric Illuminating Company, of Boston, has made arrangements to give up his position and to again take an active part in the business of Pattison Brothers, consulting and supervising engineers of this city. He will continue until January 1st to give part of his time to finishing up the construction work now in progress for the Boston Edison Company, but is at liberty from the present time to act as engineer for other concerns who may desire his services.

MR. LEMUEL E. BANNISTER, of the Westinghouse Electric Manufacturing Company, has gone abroad for a vacation of a few weeks.

THE STOCK MARKET

SECURITIES STEADY OR ADVANCING.

The results of the week go to show that conditions are steady and that in general the country is in a far more hopeful attitude of mind than it has been for a long time past. The cheering views expressed by Mr. Gage, the Secretary of the Treasury, have attracted much attention, the more because of the promise associated with them to give the country legislation looking to a sound currency as soon as the tariff is settled. Meanwhile, the tariff is moving through Congress at a good rate of speed.

Current quotations for Western Union are 79¼ to ¾, General Electric, 31½; American Bell, 229. Electric Storage Battery is reported from Philadelphia as strong and active and in ready demand.

COPPER.—There has been an active market for copper. Lake Superior was quoted at 11 cents up to 11¼. Other grades sold at 10⅝ to 10¾ for electrolytic, and 10⅜ to 10⅝ for casting stock.

MR. W. S. BARSTOW, the general superintendent of the Brooklyn Edison Company, writes: "I have always found The Electrical Engineer up to date in all recent developments of central station work. As we all know, a central station manager's time is not his own, and it is very comforting to know that there is a paper to which he can go for all his information, at the same time feeling sure that this information is correct in every detail."

MR. E. E. CUNNINGHAM, the electrician of the Valley Improvement Company, Elkins, W. Va., says: "I have been a reader of your journal for some time, and I am well pleased with it. Any electrical or steam engineer who wants to keep posted, cannot afford to do without it."

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JUNE 1, 1897.

Alarms and Signals:—

ELECTRIC BURGLAR AND FIRE ALARM. J. R. Fraser, Jr., Chicago, Ill., 583,644. Filed February 20, 1897.

A combined burglar and fire alarm system in which the burglar alarm may be rendered inoperative without affecting the fire alarm.

Batteries, Secondary:

SECONDARY BATTERY. J. H. May and F. King, London, Eng., 583,810. Filed January 26, 1897.

Method of applying a coating of India rubber to a cover for secondary batteries. Consists in first treating with a solvent of the material composing it, and applying to it while in soft condition a coating of India rubber.

Conductors, Conduits and Insulators:—

ELECTRIC CONNECTOR. F. E. Austin, Hanover, N. H., 583,589. Filed January 7, 1897.

An insulating casing having elastic closing plugs provided with pin hole apertures for the insertion of the ends of the conducting wires, and a conducting amalgam in the casing adapted to establish an electrical connection between the wires.

CONDUIT. A. L. Daniels, North East, Pa., 583,672. Filed February 10, 1896.

Consists of an inner clay tube composed of short lengths, an outer wrapping of wire, and a coat of waterproof material between the wire and the clay tube.

INSULATOR. E. Renault, Waldo, Fla., 583,692. Filed January 20, 1897.

Comprises a pin having clamping members formed integral therewith, an insulating bulb, formed with a circumferential groove in which the members fit, the bulb being provided with an interiorly toothed sleeve through which the wire passes and is held by the teeth, and set-screws located above and below the bulb for securing the clamping members together.

ELECTRIC INSULATOR. W. Christie, San Francisco, Cal., 583,787. Filed February 16, 1897.

Insulated hanger for electric wires, and comprises an insulator enclosed within a metallic casing.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. P. M. Heldt, Chicago, Ill., 583,622. Filed November 16, 1896.

Comprises a source of polyphase current, with a plurality of primary coils in circuit therewith, and a plurality of secondary coils being disposed in substantially equal inductive relation to each of the primary coils.

Miscellaneous:—

ELECTRIC GAS LIGHTER. J. Y. Parke, Philadelphia, Pa., 583,630. Filed January 2, 1897.

Details of construction.

ELECTRIC WATER FILTER. W. L. Teter, Philadelphia, Pa., 583,718. Filed June 19, 1896.

Consists in forcing the liquid in minute jets against a positive metallic electrode, filtering it and at the same time passing a current of electricity through it, and in its divided state subjecting each jet to the action of a current of electricity, then forcing the water up through a filtering medium and at the same time passing a current of electricity through the water.

VACUUM ELECTRIC ARC FURNACE. H. Eldridge, G. H. Wright and D. J. Clark, Galveston, Tex., 583,618. Filed February 24, 1896.

An upright furnace casing, a carbon lined pot-cathode and a hollow cylindrical anode supported within the cathode and forming a receptacle for the material to be used.

ELECTROLYSIS OF WATERY SALT SOLUTIONS. W. Spilker, Berlin, Germany, 583,513. Filed August 15, 1891.

A process for the production of diaphragms for use in electrolytic processes by the electrolytic process itself with the preliminary aid of an endosmotic vegetable, animal, or mineral membrane—such as parchment, asbestos, etc.

MANUFACTURE OF CARBID OF CALCIUM. J. T. Morehead, Spray, N. C., 583,498. Filed February 20, 1896.

Consists in building up the furnace wall as the formation of the carbid progresses, adding fresh charges of the material to be treated as the wall is built up, and keeping the lower end of the upper electrode at all times near the upper edge of the furnace wall.

Railways and Appliances:—

UNDERGROUND RAILWAY CONDUIT. A. G. Wheeler, New York, 583,524. Filed March 5, 1896.

A slotted conduit comprising slot-rails, supports to which they are bolted and guide rails which are secured to the slot-rail supports being inserted between the slot-rails and their supports.

ELECTRIC RAILWAY. A. G. Wheeler, New York, 583,525. Filed March 5, 1896.

Comprises a supporting bar attached to the car and carrying at its lower end a traveling contact device.

COLLECTOR FOR ELECTRIC RAILWAYS. L. J. Hirt, Brookline, Mass., 583,575. Filed September 6, 1895.

Consists of a plow having a series of contact-points on the supply conductors, and provided with appliances for cleaning and brightening the conductors.

TROLLEY FINDER. G. E. Johnson, Los Angeles, Cal., 583,868. Filed August 21, 1896.

Two arms pivoted and arranged to drop by gravity from each other in a plane transverse to the trolley wire, and means for raising the arms to cause them to straddle the trolley wire.

SELF-ADJUSTING TROLLEY. C. S. McIntire, Allegheny, Pa., 583,881. Filed February 19, 1895.

Comprises a trolley arm and wheel of lateral inclined guard fingers and a wire replacing slide adapted to raise the wire from the guard fingers and replace it in the groove of the trolley wheel.

ELECTRIC BRAKE. R. M. Hunter, Philadelphia, Pa., 583,880. Filed July 14, 1895.

Comprises a longitudinal sliding core encircling the axle and having conical friction-head, a spring acting to press the core in one direction to remove the braking action, and a solenoid having a stationary frame with a conical socket formed to receive the conical head of the core.

Switches, Cut-Outs, Etc.:—

ELECTRIC SWITCH. T. H. Brady, New Britain, Conn., 583,452. Filed February 1, 1897.

Knife switch for heavy currents.

FUSIBLE SOCKET FOR ELECTRIC LAMPS. S. H. Russell, Watsonville, Cal., 583,820. Filed December 7, 1896.

Details of construction.

LEGAL NOTES

TROLLEY FREIGHT CARS ENJOINED ON LONG ISLAND.

A temporary injunction has been granted by Justice Gaynor restraining the Long Island Electric Railroad and the National Express Company from running freight cars of the express company over the tracks of the Long Island Electric Road between Jamaica and Far Rockaway. The suit is brought by Aaron N. De Graw, property owner in Jamaica on the line of the trolley road. He claims the electric road company was organized for passenger service, and that the contract with the express company is in violation of law.

REPORTS OF COMPANIES

ADAMS-BAGNALL ELECTRIC CO.

The Adams-Bagnall Electric Company have, as already announced in these pages, recently closed a deal by which they will confine themselves exclusively to the manufacture of arc lamps, having sold their incandescent business and factory. Their late manager, Mr. Rogers, and Mr. Arnold, of their engineering corps, have gone with the incandescent business. The Adams-Bagnall Company have moved into much larger quarters, which gives them nearly double their previous capacity and the manufacturing facilities which their previous experience showed them would be desirable.

INTERNATIONAL BELL TELEPHONE COMPANY (LIMITED).—The directors elected for this company are Samuel D. Babcock, Gardiner G. Hubbard, Louis A. Von Hoffman, Richard A. McCurdy, Charlton T. Lewis, Elisha S. Converse, Ferdinand C. Thierot, Howard S. Randall, and Louis A. Thébaud.

NATIONAL AUTOMATIC FIRE ALARM COMPANY OF LOUISIANA, New Orleans, office 618 Gravier street, is going into the general electrical supply business, handling electric light, telephone and house goods supplies, putting in a complete line of these goods. Mr. E. H. McFall, general manager, writes us that he will be glad to receive catalogues and communications from manufacturers.

PROVO, UTAH.—Mr. L. L. Nunn has filed notice for a big dam to furnish water for a 10-000-horse-power electrical transmission scheme.

WINDSOR LOCKS, CONN.—It is proposed to have the electric light company pump water for the water company by motor, shutting down the expensive steam plant at the reservoir.

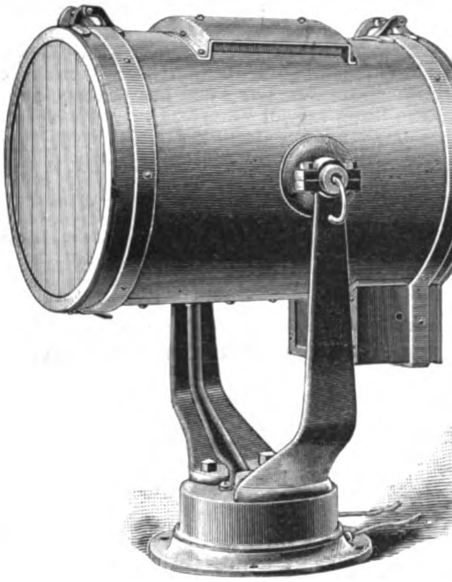
NO CHEWING.—Orders have been given forbidding the practice of chewing tobacco on the part of the operators in the larger telegraph offices of the country, and the men will have to fall back on "gum."

OLD COLONY ROAD.—It is stated that on the Providence Division of the Old Colony Road, from Forest Hills to Readville, the laying of two additional tracks later to be used in connection with the electrical equipment of this line, has been completed, and the stations moved back the necessary distance to clear the way.

TRADE NOTES & NOVELTIES

CARLISLE & FINCH SEARCH LIGHTS.

It is rapidly becoming a necessity for all steamers, whether for ocean, river or lake service to be equipped with the best modern search lights, to assist them make landings with safety and in loading and unloading freight, etc. A lamp that is coming into favor for this purpose in the West is the one manufactured by the Carlisle & Finch Company, of Cincinnati, O. The general appearance of their lamp is shown in the accompanying engraving, which is what is known as "Form 1," or lamp without pilot house steering gear. This lamp embodies all the latest and best features of search light construction.



Carlisle & Finch Search Light.

The feeding apparatus is so accurate that a variation of two volts across the arc is impossible. The lamp will start and burn perfectly when pointed in any direction, and will work as well when pointing up vertically as when in a horizontal position. Either silvered copper reflectors or ground glass lens mirrors are furnished as desired. By means of a small hand wheel in a convenient place, the relative position of reflector and arc may be changed so as to make the ray of light straight or divergent at will. The lamps are made of iron, brass or aluminum. The bases are broad and heavy, and of such width that the whole appearance is extremely symmetrical. The entire weight of the lamp is supported on hardened steel balls and the friction is thus reduced to a minimum.

It is a noteworthy fact that wherever these lamps have been installed they have invariably brought duplicate orders, which is a most flattering recommendation. The firm will be glad to send their full descriptive pamphlet, with prices, on application.

THE STANDARD ELECTRIC COMPANY'S PRODUCTS.

No electrical man, engineer or contractor, with the advances made in the use of high tension circuits, needs to be told the importance of a reliable switch, releasing the contact blades quickly and positively. The Standard Electric Co., of Reading, Pa., have placed a line of switches on the market that are particularly adapted for controlling circuits conveying high tension currents, in which class of switches breaking of the arc is the vital point. Their advertisement appearing on page xxx of this issue illustrates the device. The circuit is broken by the release of the switch blades from engagement with the pole pieces by the expansive force of a compression spring, when the lever releases the cam. The switch lever or arm in its open position, it will be noticed, shows a wedge-shaped protrusion, which, when the lever is closed, engages itself with the rounded bearing faces of steel, permanently attached to the blades. This engagement by the wedge as an auxiliary, makes the contact rigid and perfect in meeting the contacts on terminals. In a recent test for quickness in rupturing the arc, a 15 ampere double pole switch on an 80-light circuit of 220 volts, openea the line with a barely perceptible arc. The company will be glad to respond to any inquiries in regard to these meritorious appliances, and prompt shipment of all orders is promised.

THE HEINTZ STEAM TRAP.

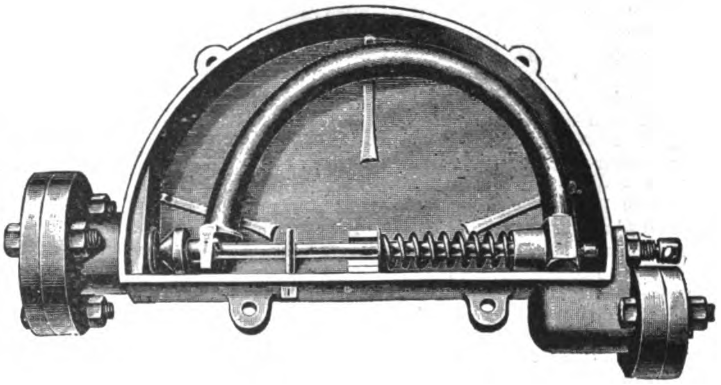
A STEAM saving device recently introduced into this country has attracted attention among steam users. The inventor of this trap, A. Heintz, a native of Alsace, was one of the first to conceive the idea that an expansion trap was, theoretically, and should be practically, the best form of this apparatus, and some twenty-five years ago began experiments on this line. After two years steady work he succeeded in producing a device that met with a fair amount of success but did not realize the inventor's ideas, and it was not until five years later, after constant, energetic application, that he finally succeeded in producing the article that he now places on the market in very nearly the same form that it now possesses.

The Heintz apparatus illustrated in the accompanying engraving consists of a tube spring which is practically the trap, and in the manufacture of this, twenty-one processes are involved, and for each individual spring three weeks' time is consumed. This is so adjusted that at a temperature of 212 degs. it holds the valve closed tight against any pressure and variation of pressure up to 200 lbs., but at 211 dgs. it is slightly open, and by the time the temperature of passing condensation has fallen to 197 dgs., it is wide open, closing again when the temperature reaches 212 degs.

The peculiar merit and economy of the Heintz system lies in the fact that it utilizes all the heat in the steam, but the instant this steam is converted into water, it is passed off and discharged into any convenient receptacle which may be placed either below or above the trap, as the latter will elevate this condensation to any height, limited only by the pressure of steam behind it.

William S. Haines, of 126 South Fourth street, Philadelphia, the sole manufacturer in the United States, claims that he can effect a saving in the fuel used of not less than ten per cent., and cites cases where the saving has been as high as thirty-three per cent.

Mr. Haines states that one single order for twenty thousand No. 1 traps was received last month from a railroad company after exhaustive tests. Inquiries addressed to Mr. Haines at 126 South Fourth street, Philadelphia, will be promptly taken care of.



Figs. 1 and 2.—The Heintz Steam Trap.

FORT WAYNE ELECTRIC CORPORATION.

The continued dull times have exerted no ill effect on the business of the Fort Wayne Electric Corporation. They have experienced a brisk inquiry and sale for all their specialties, which now range through the entire field of electric light and power. The installations of Fort Wayne lighting apparatus have been very numerous of late. The company acquired recently, as already noted in these columns, the full control of the Adams-Bagnall incandescent lamp, which has an entirely smooth bulb, without nipple, and it is understood that this will be very energetically pushed. Mr. C. S. Knight, the active manager of the company, will be present at the Niagara Falls convention.

THE BOSSERT ELECTRIC CONSTRUCTION COMPANY, Utica, N. Y., make steel boxes of every kind and description for electrical work.

P. & B. SPECIALTIES.

Mr. Frank S. De Ronde, general sales agent of the Standard Paint Company, 81-83 John street, New York, reports that during the past six months the increase of sales of their P. & B. insulating compounds and other electrical goods, particularly in the West, has been most gratifying. People who used these goods ten years ago are using them to-day, preferring not to change. The Standard Paint Company are now making a specialty of tape for re-insulating cable, preservative paints for poles and cross arms, acid proof paints for battery rooms, etc. They are also offering an excellent white and color water paint which is especially adapted for use on walls, etc. Color card and price list of this material will be gladly sent anywhere on application, and should be kept handy in electric lighting, power and railway plants.

ADVERTISERS' HINTS

HUGO REISINGER, 38 Beaver street, New York, claims the "Electra" Nuernberg carbons are the most economical and efficient manufactured.

THE WAGNER ELECTRIC MANUFACTURING COMPANY, St. Louis, Mo., illustrate an installation of 600 kilowatt 10,000 volts water-jacketed transformers at Riverside, Cal. They also set forth the merits of their 1897 induction ceiling fan motors for 16,000 or 7,200 alternations.

THE WESTINGHOUSE MACHINE COMPANY, Pittsburg, Pa., show the "Compound" 35 to 2,000 horse-power, "Standard" 5 to 250 horse-power, and "Junior" 5 to 75 horse-power styles of their engine. Their system of permitting prospective buyers to test any engine in the shops before purchasing is a distinct inducement this company extends.

THE DAYTON GLOBE IRON WORKS, Dayton, O., advertise water wheels for power transmission. They present views of a pair installed for the plant of the Boston and Montana Consolidated Copper and Silver Mining Company, at Great Falls, Mont. 3,945 horse-power is developed under a head of 50 feet.

HART & HEGEMAN MANUFACTURING COMPANY, Hartford, Conn., have lately brought out several new designs in their well known switches. Some of these are illustrated and briefly described in this issue, but full information may be obtained by requesting their catalogue "C."

ABENDROTH & ROOT MANUFACTURING COMPANY, 28 Cliff street, New York, claim that the Root boiler is the best adapted to lighting and railway station work.

THE AMERICAN ENGINE COMPANY, Bound Brook, N. J., advertise their new combination of American-Ball engine and new six-pole generators, and publish a long list of direct-connected plants they are now installing.

JACOB CLOOS, consulting engineer, Milwaukee, Wis., draws attention to his junction box for high potential alternating and direct currents, which was fully described in the February 17th issue of The Electrical Engineer, and will furnish catalogues and price lists on application.

THE OKONITE COMPANY simply state that Okonite is the best insulation for lighting and power.

THE BRUSH ELECTRIC COMPANY show their arc dynamo as it was twenty years ago, and as it is to-day. They offer reduced prices on supply parts when ordered direct.

THE OHIO STORAGE BATTERY COMPANY, Wade Building, Cleveland, Ohio, set forth the manifold advantages incident to the use of storage batteries. This company manufacture a special type for motor-cycle work.

THE STANDARD THERMOMETER AND ELECTRIC COMPANY, Peabody, Mass., advertise the Upton "Midget" enclosed arc lamp as being the shortest, cheapest and most efficient on the market.

THE FARRACUTE MACHINE COMPANY, Bridgeton, N. J., build presses and dies for cutting and notching armature discs and other electrical work.

H. M. UNDERWOOD & COMPANY, Marquette Building, Chicago, Ill., say their "Duplex" lamp guard has made "a great hit." A card dropped to them will elicit full information.

CARLISLE & FINCH COMPANY, 830 North Sixth street, Cincinnati, Ohio, are offering a hand dynamo which generates direct current, 10 volts, 2 amperes or more according to the power applied. It weighs 16 pounds, is twelve inches high and costs $6.50.

THE NORTHERN ELECTRICAL MANUFACTURING COMPANY, Madison, Wis., show a type of their iron clad motor adapted to be fastened to ceiling beams, wall beams or wherever most convenient.

THE PRATT & WHITNEY COMPANY, Hartford, Conn., build an endless variety of milling machines and machine tools. This week they illustrate their No. 2 column miller and No. 3 die sinker.

E. H. KELLOGG & COMPANY, 243 South street, New York, established in 1858, are experts in the manufacture of oils for lubricating purposes.

EMIL GREINER, 146-148 William street, New York, is supplying X-ray focus tubes, for which he claims the highest efficiency.

THE BEACON LAMP COMPANY, New Brunswick, N. J., state that they are not in the trust, but are ready to furnish in any quantity every variety of incandescent lamps and X-ray tubes as well.

THE WARD LEONARD ELECTRIC COMPANY, Hoboken, N. J., present a cut of their 1,000-light interlocking dimmer. Their recovery from the disastrous fire which destroyed their works has been exceedingly rapid.

THE GIBBS ELECTRIC MANUFACTURING COMPANY, Hartford, Conn., guarantee absolute protection to the trade in buying the Hartford switches. They say the base never breaks.

THE WALKER COMPANY, Cleveland, Ohio, illustrate the new Walker inductor alternator and cite some of its many excellent features.

THE STANDARD ELECTRIC COMPANY, Reading, Pa., advertise quick break switches and automatic time cut-outs. Both switches and cut-outs are made to suit the conditions of any circuit.

THE ADAMS-BAGNALL ELECTRIC COMPANY, Cleveland, Ohio, advertise arc lamps in every variety.

THE NATIONAL CARBON COMPANY, Cleveland, Ohio, are manufacturing cored and solid carbons, carbon brushes and a large variety of carbon specialties.

THE BOSTON MOTOR COMPANY, Boston, Mass., furnish X-ray apparatus, experimental supplies, motors, etc. They will send a catalogue on receipt of stamp.

HAMMACHER, SCHLEMMER & COMPANY, 209 Bowery, New York, make telephone box locks one of their specialties.

CHAS. BESELER'S SON, 218 Centre street, New York, is advertising high grade stereopticons, magic lanterns and accessories.

THE PRENTISS CLOCK IMPROVEMENT COMPANY, 49 Dey street, New York, are prepared to furnish anything electrical in connection with clocks. Their catalogue 5697 contains full information.

HENRY W. BULKLEY, the sole manufacturer of the Bulkley "injector" condenser, illustrates the apparatus similar to that installed in the Paterson (N. J.) Edison Company's station described in The Electrical Engineer of December 9, 1896. This condenser requires no air pump, "safety" floats, vacuum valves, exhaust check valves, etc.

THE ELECTRICAL ENGINEERING AND SUPPLY COMPANY, Syracuse, N. Y., carry at all times a full line of sockets, switches, cut-outs, wall boxes, junction boxes, switchboards, etc.

THE NON-POLARIZING DRY BATTERY COMPANY, 347 West Broadway, New York, advocate the use of the "O. K." dry battery and publish a list of dimensions and output of several types of cells.

THE IRON CLAD RHEOSTAT COMPANY, Westfield, N.J., state that there are 2,500 of their theatre dimmers in use.

R. B. COREY, 711 Havemeyer Building, New York, is the New York agent for the "Columbia" incandescent lamp, "Simplex" wires and cables, "T Z R' weather-proof and rubber covered wires, and underground cables.

THE ELECTRICAL EXCHANGE, 166 South Clinton street, Chicago, are offering some bargains in alternating generators, direct current dynamos and motors, arc lamps, instruments, etc.

THE AMERICAN CARBON CO.'S carbons are carried in stock by the Chicago Edison Co., Chicago, Ill.; the Peck Electrical Co., New York City, and the Brooks Follis Electric Co., San Francisco.

WILLIAM S. HAINES, 122 South Fourth street, Philadelphia, Pa., is the sole manufacturer for the United States and Canada of the Heintz Steam Saver. It is fully described elsewhere in this issue.

AMERICAN RHEOSTAT CO., Milwaukee, Wis., advertise an electric controller that "is not built for the repair man and does not make you think it's the fourth of July when it operates."

THE CENTRAL ELECTRIC CO., 173 Adams street, Chicago, give a couple of pointers to probable purchasers.

OTIS BROS. & CO., New York, illustrate one of their electric passenger elevators and give several reasons why it is one of the most desirable.

THE ELECTRIC APPLIANCE CO., 242 Madison street, Chicago, Ill., are headquarters for porcelain goods, carrying a full line in stock. They are ready to fill orders with despatch.

DIEHL MANUFACTURING COMPANY, Elizabethport, N. J., have brought out several new designs in their famous fans this season.

FORT WAYNE ELECTRIC CORP., Fort Wayne, Ind., advertise the "Wood" station instruments in the construction of which no springs or permanent magnets are used.

THE INTERIOR CONDUIT AND INSULATION COMPANY, 527 West Thirty-fourth street, New York, claim their system of interior wiring to be the standard.

THE SHELBY ELECTRIC COMPANY, Shelby, Ohio, say that by the use of their lamps, 20 per cent. is saved in economy and 30 per cent. in life. They are now in a position to fill all orders promptly.

THE STANDARD THERMOMETER AND ELECTRIC COMPANY, Peabody, Mass., who have met with so much success in introducing their latest lamp, the "Midget" enclosed arc, which they claim to be the shortest on the market, are represented in New York by J. H. Bunnell & Co.; Chicago, The Electric Appliance Company; Philadelphia, Etherington & Co.; San Francisco, Dunham, Carrigan & Hayden Co.

J. JONES & SON, 67 Cortlandt street, New York, advertise switches, switchboards and panel boards, as well as electrical supplies.

THE BERNSTEIN ELECTRIC COMPANY, Boston, Mass., continue to sell their well known incandescent lamps.

THE AMERICAN ENDOSCOPIC COMPANY make it a specialty to supply miniature lamps for decorative purposes.

S. F. B. MORSE & COMPANY, Chicago, carry a stock including wires and cables, arc lamps, incandescent lamps, rheostats and theatre dimmers, and general electrical supplies.

THE ELECTRIC PROTECTION COMPANY, Philadelphia, Pa., advertise the Hunter push buttons as the best thing in that line.

THE EDDY ELECTRIC MANUFACTURING COMPANY, Windsor, Conn., state that it is now sixteen years since their apparatus was first put on the market. Their direct-connected generators and motors are recognized as standard the world over.

THE W. S. HILL ELECTRIC COMPANY, New Bedford, Mass., remind the public that to make and sell switches and switchboards is their business, and that they are doing both.

THE ELWELL-PARKER ELECTRIC COMPANY, Cleveland, Ohio, carry a full line of belted and direct-connected motors for all conditions of service, direct connection to machines being one of them.

QUEEN & COMPANY, Philadelphia, Pa., note the advantages of their adjustable vacuum X-ray tubes.

AHLM-EDWARDS ELECTRIC COMPANY, who recently moved to larger quarters in Cleveland, are building an excellent line of dynamos and motors. They will cheerfully reply to any requests for detail information.

McLEOD, WARD & COMPANY, New York City, advertise ceiling fans, ventilating fans, desk lamps and spark arresters.

THE AMERICAN ELECTRIC HEATING CORPORATION, Boston, Mass., have made "a hit" with their Universal field rheostat and will introduce an automatic motor starter in thirty days.

A. K. WARREN & COMPANY, New York, illustrate their dynamo brushes, which they claim to be the most economical on the market, as by means of the holder every part of the brush is utilized.

NEWTON APPLIANCE COMPANY, New York, illustrate and describe some of their specialties in switches, fuse "bugs," etc.

THE INTERNATIONAL ARC LAMP COMPANY, New York, call attention to something new in that line.

ANCHOR ELECTRIC COMPANY, Boston, advertise switches of all kinds.

KEYSTONE ELECTRIC INSTRUMENT COMPANY, Philadelphia, Pa., will have their headquarters in Parlor E of the Cataract House during the convention, where they will give all information regarding their high grade instruments.

F. N. ROEHRICH & CO., the specialists in machinery designing, have removed to more commodious quarters at 102 Fulton street, New York.

EDWARDS & CO., 144th street and Fourth avenue, New York, advertise a great variety of specialties, including door openers, self-fastening desk pushes and lock gravity drop burglar alarms.

THE THRESHER ELECTRIC COMPANY, 26 North Main street, Dayton, Ohio, show one of their motors direct connected to a web printing press. The slow speed at which these motors operate and their general construction render them well adapted for power work.

THE D. & W. FUSE COMPANY, 53 Ahorn street, Providence, R. I., are doing a large business in their non-arcing fuse and safety devices for alternating, motor, railway, lighting, telephone and fire-alarm circuits, and claim them to be absolute protection from short-circuit or overload.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., who commend the Holly system of heating in utilizing waste steam, quote a letter from one of their customers who says that their receipts from this source enable them to pay eight per cent. dividends on an investment of $100,000, which includes their electric lighting plant and steam heating apparatus.

THE STANDARD PAINT COMPANY, 81 and 83 John street New York, invite those interested to write for prices on the P. & B. specialties. These have long been recognized as standard, and the excellence of their quality is indisputable.

W. R. BRIXEY, 203 Broadway, New York, continues to sell "Kerite" wire and cables. Kerite has a thirty-one years' record and is still holding its own, becoming more popular every year.

THE IDEAL ELECTRIC CORP., Thirteenth and Hudson streets, New York, illustrate their alternating long-burning arc lamp. A card to them will obtain full details as to what this lamp will and will not do.

THE WHITE THERMOSTAT COMPANY, Providence, R. I., have an insulating wire support that is really worth considering. Its simplicity and efficiency are hard to excel.

THOS. MUIR & SON, Detroit, Mich., have met with much success in introducing their new motor starter, combining simplicity, durability and efficiency and made for 110, 220 and 500-volt currents.

THE GENERAL ELECTRIC COMPANY will be largely represented at the convention and will respond to any inquiries regarding their several systems of complete central station equipment.

NEW ENGLAND NOTES

AMERICAN ENDOSCOPIC COMPANY, Providence, R. I., are very busy on orders for their surgical, dental and bicycle lamps. They are specialists in all high-grade miniature lamps.

C. H. McEVOY, Lowell, Mass., reports a satisfactory business in telephone cords. Mr. McEvoy has been manufacturing telephone cords almost from the time the telephone was invented, also switchboard cords, medical battery and bell cords. They are of superior make and widely used throughout the country. Mr. McEvoy will take pleasure in mailing catalogue and prices to any address on application.

L. E. KNOTT APPARATUS COMPANY, 14 Ashburton Place, Boston, Mass., are filling good orders for physical and electrical apparatus. They are manufacturers and dealers in these goods.

GLOBE ELECTRIC LAMP COMPANY, Malden, Mass., have enlarged their plant and put in new machinery to increase their output.

JOHN BECKER MANUFACTURING COMPANY, Fitchburg, Mass., are receiving large export orders for their milling machines.

BOSTON MOTOR COMPANY, 17 Batterymarch street, Boston, Mass., have issued a very interesting 1897 catalogue, which contains several tables and other valuable information, and shows also a full line of motors for battery alternating and direct current purposes. It includes also Röntgen ray apparatus, and a variety of experimental electrical supplies. A copy will be sent to anyone interested on receipt of two cents for postage, and prompt attention will be paid to any orders or requests for information. Requests for catalogues should mention the 1897 edition.

WESTERN NOTES

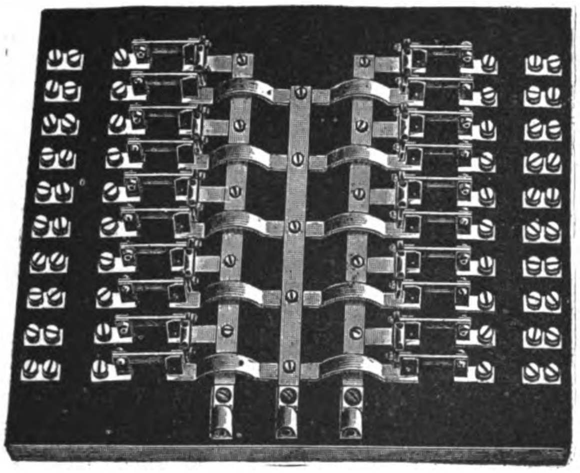
A. M. MORSE has removed from 1249 Marquette Building, Chicago, to suite No. 1108 and 1109 same building. He will make a specialty of high grade engines for electrical service, both Corliss and high speed type. Mr. Morse has had a wide experience in steam engineering work, and has equipped many of the representative power plants in the southwest. For the past five years he has been the selling agent of the Buckeye Engine Company, but severed his connection with that company June 1st.

ELECTRIC APPLIANCE COMPANY.—The protection of electrical machinery from damage by electrical storms is al-

THE JONES PANEL BOARDS.

THE latest thing in panel boards is the unique idea embodied in the boards built by Messrs. J. Jones & Son, of 67 Cortlandt street, New York.

As shown in the accompanying engraving, instead of raising up the mains, as has been done in the past, the mains are "jumped" by the branches by means of a half-loop in the same strip. The main bars thus rest directly on the branch bars, reducing the number of joints to a minimum, lessening thereby the resistance at the contacts and at the same time reducing the cost. The engraving shows a 3-wire main with 2-wire branches.



JONES & SON PANEL BOARD.

NEW YORK NOTES.

KIELY & MUELLER, 7 to 17 West Thirteenth street, New York, are the inventors and manufacturers of the Champion return steam trap, Eureka pressure regulator, and positive-acting pump governor. They handle a great many other steam specialties and have recently installed their goods in the new "Astoria" Hotel, Delmonico Building and Sherry Building.

PEERLESS RUBBER MANUFACTURING COMPANY, 16 Warren street, have just issued a very tasteful circular, literally in all the colors of the rainbow, devoted to an illustrated description of their leading specialties, Rainbow, Honest John, Hercules and Peerless packings, as well as the Eclipse Sectional Rainbow Gaskets. Our readers should get a copy of this circular.

MR. A. D. FRENCH, the New York agent of the Williamsport Wooden Pipe Company, has been obliged to remove to larger quarters in the Edison Building, 44 Broad street, in order to handle his increasing trade. Besides handling conduit, he has a large trade in octagonal poles, and keeps a stock in New York ready for quick delivery. He also controls the output of two mills in the South, and has a large stock of poles on hand for shipment.

ROOT BOILERS.—One may depend upon the Root boiler for safety and economy and efficient service. It has been upon the market for thirty years and its merit is unquestioned. There is an attractive advertisement of the manufacturers, the Abendroth & Root Manufacturing Company, in this number, and our readers are advised to give it their attention.

NEW JERSEY now has in force a law compelling trolley companies to vestibule their cars in winter.

HARRISON SAFETY BOILER WORKS, Philadelphia, have recently shipped a 1,000-horse-power heater to the Central Electric Company, Lexington, Ky., and a 500-horse-power heater to the Memphis Light and Power Company, Memphis, Tenn.

MR. A. L. REINMANN, for many years general superintendent of the Sawyer-Man lamp factory, is now general superintendent of De Laval's Svea lamp factory at Stockholm, Sweden. It is one of the largest establishments of this class, having a capacity of 10,000 lamps a day. They own their own gas works and glass house, and use some Berrenberg metallic pumps.

FLUSHING, N. Y.—The Queen Construction Company are erecting in Flushing, L. I., N. Y., a new electric light plant. The building is divided into two portions, a boiler house 40 ft. x 42 ft., and an engine and dynamo room, 43 ft. x 71 ft. The walls are of brick and have substantial stone foundations, and the roof is of iron, covered with metal covering. The building, when completed, will be absolutely fire-proof. The roof of the engine and dynamo room is lined with the Berlin Iron Bridge Company's patent anti-condensation roof lining, which prevents condensation of moisture on the under side of the roof, a result which is absolutely necessary to obtain in a building filled with electrical apparatus. The Berlin company have the contract for furnishing and erecting the steel frame work and the covering.

ELECTRIC LIGHTING

MUNICIPAL LIGHTING.[1]

BY W. WORTH BEAN.

THE subject to which I would respectfully invite your attention is one of the most vital questions, and of the most momentous importance—not only to the profession to which we have the honor to belong, but also to various commonwealths of which it is our pride to be citizens—that has ever arisen in this advanced electrical era. Municipal ownership of electric lighting plants, the most discussed of all the questions of municipal polity, is the more insidious that it comes dressed in the sheep's woolly garb of a philanthropist, which to the uninitiated and ignorant has an alluring and plausible aspect, but to the experienced are plainly visible the wolf's deadly fangs, which have, in every instance, sooner or later lacerated the taxpayer. The authors and promoters of this alluring scheme are either visionary theorists, who have no practical knowledge of its manipulation, or unscrupulous politicians who, desiring to pose as benefactors to the municipality, hope to ingratiate themselves in the hearts of the voter and thus secure political plums for themselves and their henchmen. That there are many honest supporters of this political fad who, having been deceived by beautiful but false reports from cities which are experimenting with this question, are misled by political demagogues, is undeniable.

The tidal wave is sweeping over our land, and certain municipalities are now on the crest, but it will not need the average period of depreciation in a plant for the wave to subside and leave the wrecks stranded with increased burdens and depleted treasuries. Already cities have sold their plants, paying dearly for their experience, and others are looking for buyers, in order to unload their "white elephants." Municipal ownership is contrary to the spirit of republican institutions.

Government, whether national, State or municipal, was instituted for the purpose of protection and not production. It would be just as reasonable for the city to enter any pursuit, such as farming, or as a grocer, or keep a sawmill to saw its own material for sidewalks or paving, or manufacture shoes for its citizens, or run a saloon for the profit there is in it, as for it to enter the field of lighting. Just as sure as a nation becomes a commercial producer, competing against its own citizens, just so sure will the seeds of its own disintegration be sown.

Municipal ownership is a source of danger to the commonwealth, in that it affords a great opportunity for fraud. Municipal corruption is so common and so well known that it needs no argument to prove the danger of opening a new avenue of power in the hands of unprincipled public officials. In this business there are a number of important, and ought to be well salaried, offices, which can be used to great advantage by political manipulators to further their own ends to the detriment of the city. In the State of Michigan one political party had been in power for thirty-four years until 1891. A member of the old party was elected to the Senate and introduced a bill to benefit Coldwater, Mich., and this has been the Mecca of the municipal advocates ever since. It has been the oasis in the desert where they could get sweet morsels to roll under their tongues to advocate the scheme of municipal ownership. I venture to say that more than a score of towns and cities have charged up expenses for the examination of this delectable plant, and from their own printed statements I am willing to qualify that the figures are not as they should be made. Reports come from Grand Haven, Mich., that through political influence a competent electrical corps has been discharged to make room for inexperienced friends of the "powers that be." "To the victor belong the spoils" is a policy followed with unswerving fidelity by a great many city officials. Scandals from our great cities in regard to employés, inspectors, officials and boodle aldermen, should teach us to avoid throwing this enterprise, involving hundreds of thousands of dollars, and positions of the utmost importance to the city, into the maelstrom of municipal politics.

Municipal ownership is unjust to the electrical plant now in the field. The central station man has, through his industry, ingenuity and executive ability, built up a large enterprise. The city has invited him to invest thousands of dollars, not only of his own money, but also the money of its own citizens, with no immediate show of dividends, and, in some cases, barely sufficient income to pay the running expenses and interest on the bonds during a period that will amount from one-half to the whole of the average amount of time allowed for depreciation of the plant. The central station man during this time has been harassed with the anxiety of meeting the fixed charges, maintaining the credit, providing a reserve fund to meet loss by fire, wind storms and burned-up apparatus, and cheering up despondent stockholders who have nothing to show for their money but the rosy-hued prospect that, at some time in the near future, there will be an adequate dividend to compensate them for their risk, and now, when these hopes are about to be realized, in a modest degree, they are confronted by municipal ownership. He must either compete with the city—which, through ignorance, will furnish lights below cost—or sell out. The latter proposition is impossible, for he cannot hope to dispose of a plant that has depreciated 50 or 75 per cent. without great loss, therefore he is compelled to continue in business with his former heaviest consumer, now his strongest competitor, with the prospect of having to renew his plant within a very short time, at a heavy expense, and knowing full well that there is room for but one paying plant in a city of that size. Such conduct on the part of the city amounts to the indirect confiscation of property; obtaining a competent and effective service for years without profit, holding out the alluring representations of a future gain.

Municipal ownership is unjust to the taxpayer. That through ignorance or willful errors in keeping accounts it is certainly true, in most cases, that lights are furnished to the city and private patrons at a loss, and the deficits charged to some other accounts. Very few of its citizens are able to take the lights at the reduced price, for the great majority of its citizens are day laborers, who are paying for their homes, and cannot afford to take the lights even at any price, but who eventually must help to carry the burden of the ever-increasing loss, thus making the many help pay for the luxuries of the few. Municipal ownership has cost the city of Hamilton, Ohio, $575,000. It is reported that an order has been made to discontinue the electric lights, on account of lack of funds. This has been a very expensive experience for Hamilton, and the taxpayer who has burned nothing but an oil lamp now helps to pay the bill.

The result, in most cases, will be less efficient service than under the competitive system. Central station men who have been in the business for a long time, and who have had years of experience, are, without doubt, the most competent to give the best service of the times. He surrounds himself with expert electricians and a corps of able assistants who have been educated in the business and retain their position by the strictest attention to duty. He is continually devising means for improving his service, not only in employés, but also in the latest improved machinery. On the other hand, municipalities change their officials frequently, and new men take control. Councilmen who oftentimes are not even good business men, and have no knowledge of apparatus and electrical affairs, pass on the purchasing of supplies and the competency of electricians and engineers, deposing experienced incumbents and apportioning political plums to friends of but ordinary ability. The men now in control attempt to compete with electrical experts and competent engineers of long experience, and about the time when they are beginning to understand their plant and how to save loss—in a year, or possibly two—the Council changes, and they must step down to make way for those of even less ability. Again, in smaller cities councilmen are often elected on the single issue of economy, and in order to fulfill the expectations of their constituents, they must cut expenses. The first attack is made on the official salaries, which results in filling responsible positions with inefficient men. Experts cannot afford to educate themselves for positions commanding low salaries and subject to the vicissitudes of municipal politics, and we all know too well the cheap men in this business are the most expensive. Then, again, the economical councilmen will object to improving the plant, which will require vast sums in replacing that which has but lately cost so much, and for which they have not as yet finished paying. This is especially so if the improvements are demanded in a time of financial depression, and when taxes are already too high.

---

[1] Abstract of paper read before the National Electric Light Association, Niagara Falls, N. Y., June 8–10, 1897.

The glowing reports from cities that are experimenting with this question are unreliable and misleading, except to the electrical profession. In some cases, where the plant is new and there is no perceptible depreciation, and where they have providentially escaped accident or disaster, no doubt these statistics are honestly, though ignorantly, compiled, deceiving the taxpayer into the belief that their venture is a glorious success. The engineer's salary and the coal bill are often charged to the water department, and the water consumer helps pay the electric light bill.

In most instances the item of interest on the outstanding bonds is charged instead of interest on the entire plant, and 4 per cent. depreciation is charged, whereas from 10 to 15 per cent, should be the rate. In some cases losses by fire are not accounted for; in others accidents are never charged. The loss to the city of the taxes that would be paid in by a private corporation is not computed, and in a great many cases the accounts are so mingled with other departments that it is impossible for even the officials themselves to tell how much the lights for street purposes cost the city.

I have personally visited Niles, Kalamazoo and South Haven, Mich., and I know that these cities are paying more for their lights than their official reports show what they cost, and yet they are considered among the list of those who are successful with municipal lighting. The city of Detroit has probably the finest equipped plant in the State of Michigan, and operated under the most advantageous circumstances, and yet she pays $100 in round numbers per lamp for 1,483 lamps, under municipal ownership, while St. Joseph and Benton Harbor, under the relentless pressure of a private corporation, only pay $90 on an average, for sixty-two lamps. Tipton, Ohio, and Marquette, Mich., had serious accidents, and the deluded taxpayer, with his eyes partly open, refuses to vote more money for such a hazardous enterprise.

At this present writing municipal lighting has not passed through its most dangerous period, and its is difficult to predict its final result. It is now but at the dawn of its existence, but a December day will be long in comparison with the life it has to run, for when bonds are to be redeemed, accidents befall the plant, and a depreciated plant is to be renewed, then comes the trying ordeal, and woe be to the city that has not provided against that day, but has wasted its substance in riotous living, for then it will be found to have nothing left for its existence but the husks of "Municipal Lighting."

PROFITABLE EXTENSIONS OF ELECTRICITY SUPPLY STATIONS.[1]

BY ARTHUR WRIGHT, BRIGHTON, ENG.

THERE are many central stations which, very soon after starting the supply, have to face extensions of plant and mains, and generally such necessity for extensions has been regarded as an unmistakable proof of commercial success. That this is not necessarily so, many of us have found, as it is obvious that no extensions are warrantable unless a definite profit can be assured from them.

No company should be called upon to supply electricity to any one at a loss, notwithstanding the common impression that it is necessary in electricity supply business to take the bad customers with the good, and the author shows in this paper that it is quite possible to devise a simple and equitable tariff by which a profit to the supply company, as nearly as is commercially practicable, is assured from every consumer; and, moreover, that only by adopting such a tariff of approximately equal rates of profit from all consumers can central station managers hope to get the use of electricity generally adopted for all the many purposes it naturally lends itself to.

Owing to the enormous development of the business of electricity supply for power transmission, for traction and other purposes, many central station managers have lately devoted most of their energies to the supply of electricity for those uses. The author, on the contrary, firmly believes that there exists even a larger and more profitable field for electricity supply ready at hand in every town, waiting only to be tapped, and refers to the supply of light to the thousands of domestic lamps required by the middle classes in their homes. This profitable domestic supply, which is largely used after business hours, need in no way interfere with the much-catered-for power supply, the value of which the author fully appreciates. Another enormous field for profitable extensions is to be found in the smaller and lower classes of stores, saloons and business houses that trade until late in the evening.

The author doubts the possibility of much financial success attending the efforts of central station managers until they dismiss from their minds the idea that large consumers' bills necessarily mean large profits, as very frequently the reverse is the case. His contention is that, if an equal rate of profit be charged to all consumers of every class and size, the field for profitable extension is practically boundless.

It may be argued that if the principle of equal rates of profit from all consumers be carried into effect, it might result in a serious loss of revenue to the supply stations, owing to the large but short-hour consumers objecting to the higher rates thereby necessarily charged to them.

A perfect answer to the short-hour consumers, who object to pay a higher rate than their long-hour neighbors, is that under no circumstances whatever ought their supply to involve a loss to the supply company or increase the charge on the more profitable classes, as it is obviously very sound commercial practice in every business, without exception, to encourage the profitable, even at the risk of losing some of the profitless, business.

If the principle of a sliding scale based upon the more or less prolonged use of the maximum demand is correct, then, on every consideration of practice and of policy, it should be applied to each consumer without distinction. Uniform rates mean that, if high, they discourage the only class of business yielding profit; and if low, mean a heavy loss on supplying short-hour consumers, which they directly encourage. Moreover, a uniform rate can never be so low for the supply of electricity to long-hour consumers as charges on an equitable sliding-scale system.

It may be said that many managers have long ago introduced the system of giving discounts in proportion to the number of lamp hours consumed per lamp installed per annum. The author maintains that, for anything else than street lighting, this system must have a very pernicious effect on the development and extension of the supply business, for the following reasons:

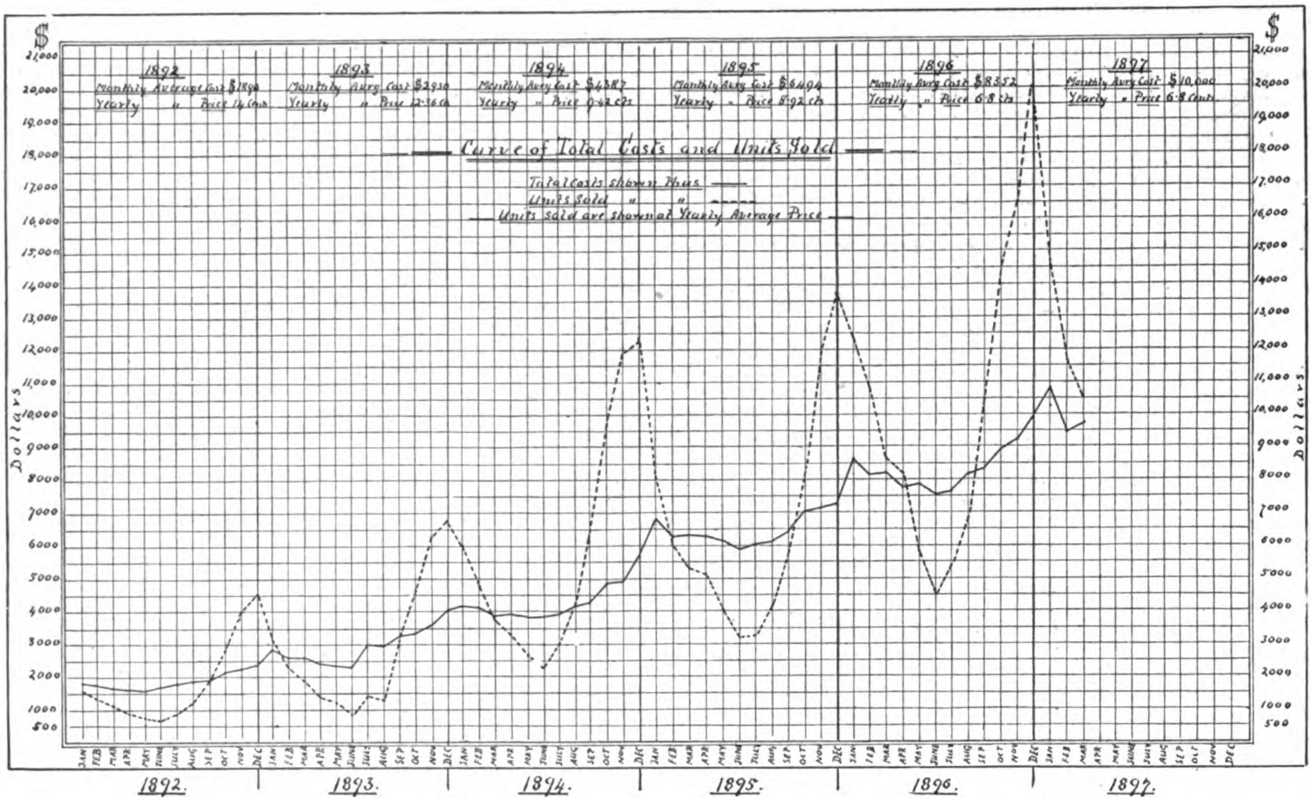
First, as the discount given is frequently inversely as the connected load (a strange method surely of encouraging the public to give a whole-hearted support to electric lighting), a consumer usually installs only those lamps he can use very freely, and, under this scale, the longer he runs them the larger will be his "bounty" in the shape of discounts; as he knows very well that if he installs any less frequently used lights, his consumption per lamp, and, consequently, the discount given him, will decrease, so he stops short of the number he would like to use, and electric lighting remains for him a luxury strictly confined between the limits of certain business or social requirements. The economic disadvantage of this method of charging, then, is that it tends to contract the load curve and drive up the peak, which seem to the author fatal to this system. By this method of discounts, hotels and private residences, which afford probably the most profitable field for electricity supply, would be charged at a rate so high as to prohibit the general wiring of them, although, by their being generally wired, their load curves would be so spread out as to make them highly desirable consumers. This method of giving rebates must also prevent large business establishments from wiring their entire premises, although, probably, the lights would be used in the upper residential parts when those on the lower floors have been extinguished.

The second objection is that in practice the author maintains it is impossible, in a large business, to ascertain with sufficient accuracy throughout the year the wired capacity of all the consumers' premises. The third great objection is the inexpediency and great expense of insisting upon the necessary domiciliary visits in all parts of private houses, hotels, etc., which this system requires.

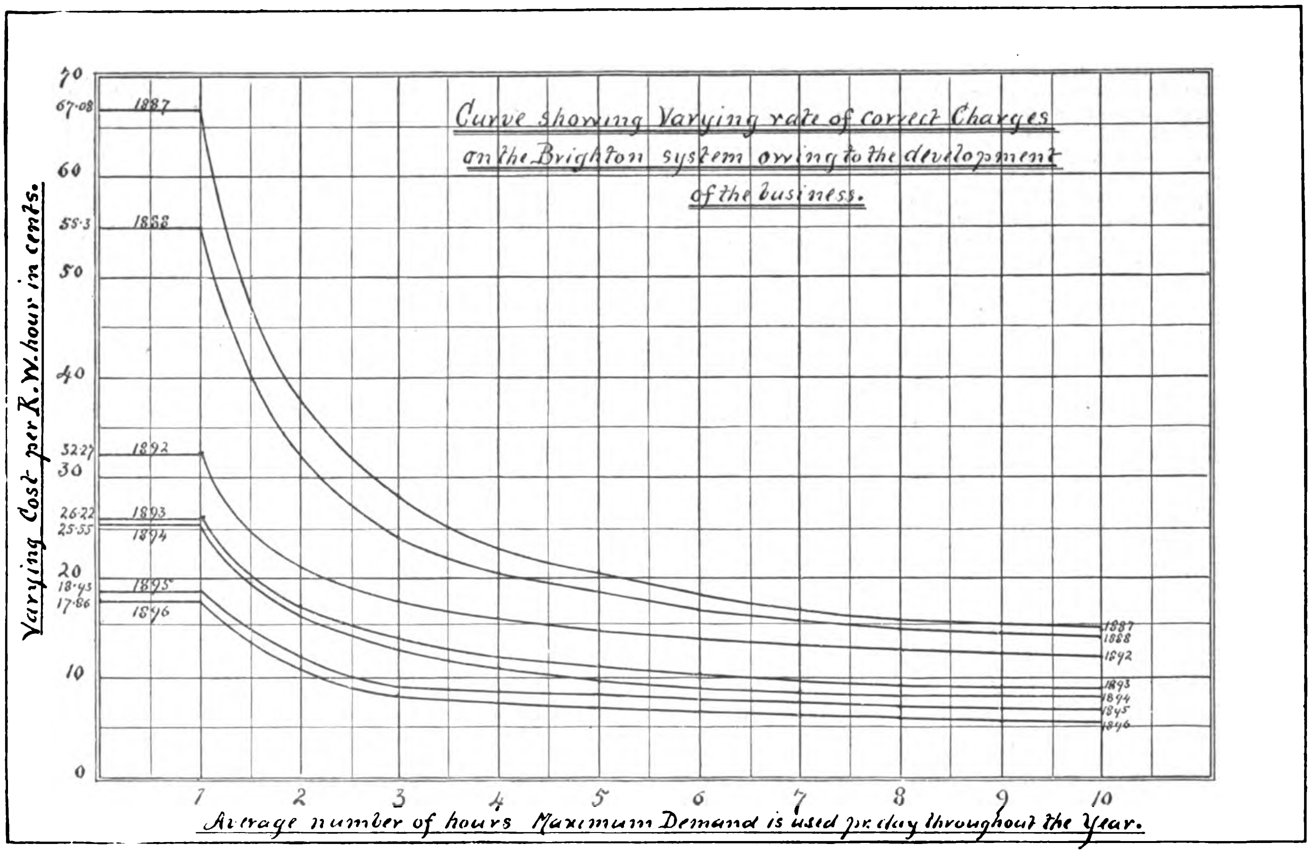
Fortunately, there is a much cheaper way of determining the consumers' true demand on the station for supply, consequently the true basis on which the charges should be made—viz., by measuring the greatest rate at which they usually require to be supplied with electricity. Another system now very much in vogue, but having equally bad effects in preventing the profitable development of supply stations, is the unsound practice of charging a higher price for electricity consumed in lamps than in motors or other current-consuming apparatus. The author maintains that the isolated plant question can also, by a judicious tariff, be turned into a blessing, instead of a curse, and his experience leads him to believe that there should be little difficulty in obtaining practically the whole of the profitable part of this business as regular consumers, instead of irregular worries. By no other method than that of an equitable sliding scale can this particular and generally very profitable business be obtained. It is well known that isolated plants are generally only installed where the demand for electricity is of a lengthy nature, consequently they would form a most desirable class of consumers if their permanent supply could only be obtained. That the result of an equitable sliding scale is to get this class of consumer on a central station supply, is shown in Brighton, England, where, since the sliding scale has been adopted, several valuable isolated plants have been secured to the supply station mains, and not a single new one has been installed in that town.

---

[1] Read before the N. E. L. A. Abstract.



at varying hours, and on the same principle encouraging consumers to install lamps that will be used at different times of the day and night. This diverse supply in a town obviously means a much less plant capacity than would be the case were all the lamps required for the same purpose and at the same time. In the town of Brighton, where the actual demands of all the consumers are accurately known, and where the use of electricity is very evenly divided between residences and stores, this diversity factor is now no less than



Another excellent method of profitably extending the business of central supply stations, is catering for, as much as possible, different classes of consumers requiring electricity one and one-half; or, in other words, if all the Brighton consumers were to require, simultaneously, their ordinary maximum supply (not their wired capacity), the generating plant of the station would have to be increased very nearly 50 per cent.

In the author's opinion, it is very much more important to run, very soon after the starting of the station, mains in all districts of the town in which artificial light is used late in the evening, although this may be in the districts of the poorer classes of consumers, than it is to spend it on coal-saving refinements, or in running large mains in districts occupied by immense early-closing stores or by the mansions of the wealthy; both classes being very expensive to supply, because of the short daily use made of the plant by the former, and the latter's frequent and lengthy absences from home, or the erratic nature of their demand.

The author would specially point out the true economy of a liberal supply of distributing mains, which can be made to serve the double purpose of supplying the street lamps as well as the general public. In this connection he questions very seriously the wisdom of the practice, resorted to by many central station managers, of running special mains and systems for the sole supply of the public street lamps, as by so doing they needlessly increase the total cost of supplying the whole of the requirements of the district.

The author thinks that insisting on a high initial rate of charge per kilowatt hour, or lamp hour, being maintained to each consumer until the annual cost of getting the plant in readiness to supply his maximum wants has been covered, and then substantially reducing the charge for the subsequent consumption, forms the basis of a perfectly equitable tariff, applicable to all stations and conditions of supply.

As the knowledge of the profit-earning capacity of any electricity supply station so obviously depends upon the correct method of determining the cost of supplying electricity, the author thinks that the accompanying tables, relating to the development of a supply station in the fairly representative English town of Brighton, will be found interesting. The consumption per inhabitant at Brighton is far and away ahead of that in any other town in the United Kingdom; viz., seventeen kilowatt hours consumed per inhabitant this year. The columns of the tables have been arranged in a form which will enable company managers to compare their results with the figures given.

The first small station was built on the usual pioneering lines adopted by many companies before security of franchise could be sufficiently assured to tempt capitalists to put much money in the concern, and the second on the modern lines of a permanent station possessing an absolutely secure franchise. As both concerns, in their respective years, were quite free from any promoters' paper capital, and always gave a supply whenever and wherever called upon to do so, the author sees no reason why the figures given should not form a basis for estimating the cost of supplying electricity under the most diverse conditions, by the necessary alterations being made in the cost of capital, coal, etc., and thereby enable any manager to find out the proper basis upon which to construct an equitable tariff for any particular town or condition of supply.

Columns have been inserted in the tables giving equitable charges that should have been made to the consumers during the different years on the two systems of charging advocated by the author, the first being based on the principle of charging the amount shown in Column 9, of Table I., per annum per maximum kilowatt demanded by each individual consumer, and then charging all the electricity consumed, quite irrespective of the purpose for which it has been used, at the rates given in Column 10 of the same table; and the other tariff, which is commonly known as the Brighton system, of charging a sufficiently high price per kilowatt hour consumed, until all the costs the company are put to in standing-by have been covered; these figures being given in Columns 11, 12 and 13, respectively, of same table. The fact of this system having been adopted in about thirty English towns will convince the members of its commercial practicability.

On this tariff it is advisable to make the difference between the initial price and the reduced price as marked as possible.

In the preparation of the tables, the author has employed the method of cost analysis by differences, explained at length in his paper before the London convention of the Municipal Electrical Association in 1896. In arriving at the total charges against the revenue accounts for the respective years, he has assumed that all stockholders would be quite willing to invest their money if 5½ per cent. on it were put aside out of revenue for the purposes of redemption and depreciation, and at the same time there was a reasonable chance of their getting another 5 per cent., at least, for the use of their money. He regards this as sufficiently liberal, as, so far as his knowledge goes, very few electricity companies set aside so large a percentage as 5½ per cent. on the whole of the capital for depreciation and repayment of capital, exclusive of dividends. With this provision the author has prepared the columns already referred to, showing what the tariff should have been to have produced this satisfactory result.

In a perfectly equitable system of charging, which, in the author's opinion, will generally be found synonymous with the soundest commercial tariff, it is obviously correct to make every one, whether using electricity for power or lighting purposes, pay the cost the company is put to in preparing the plant to supply the individual consumer's demand. Column 9, on Table I., is therefore given, showing the cost of so doing during the various years, and it is obviously inadvisable to look for a profit on this expenditure, or on the service rentals, but to make the whole of the net profit for dividend-paying purposes on the amount of the electricity actually consumed.

It must be understood that these tables have been prepared without making any arbitrary assumptions, and that the various amounts for running, standing-by, and service rentals have been ascertained by the aforesaid method of differences and by a close analysis of the stations' costs sheets.

It will be seen from Column 5, Table III., that, at Brighton, where coal on the average costs about $5 a ton, delivered in front of the boilers, the cost of producing the electricity has always been very small compared with the cost of getting everything ready to supply.

The author need hardly remind company managers that where coal is relatively cheaper, or water power is the source of energy, this proportionately large amount of standing-by costs will be still further increased.

It may be thought that all this great cost of putting the station in a position to run, compared with the cost of actually running the machinery, will practically disappear with a large extension of the motor supply business. This, in the author's opinion, is a complete fallacy, as the lighting load in any town will be very similar, however general the supply may become, and whether a constant day load is added to this or not makes no difference at all in the relative cost of supplying lamps one hour or, say, four hours. Until storage batteries become much cheaper than steam generating plants, the ratio of the standing costs to the running cost for lighting purposes will remain high.

As the standing charges of late years at Brighton have been found to rise nearly in proportion to the maximum annual load on the station, the author, in estimating the cost of supplying any consumer, debits him with an amount of the standing charges in proportion to his maximum call for current.

The author calls particular attention to Column 4, Table V., showing the enormous increase in the sales per maximum kilowatt load on the station that has occurred since the sliding scale of charging was adopted, at the beginning of the year 1893. From the column it will be noticed that this prolongation of the use of the plant has been no less than 54 per cent. in four years, and it is perhaps needless for the author to point out what a great effect this has had in reducing the cost of production, as, with coal costing even the high price it does at Brighton, an improvement of the load factor of only 3 per cent. has the same effect in reducing the total cost of producing electricity as if the coal bill had been reduced 15 per cent.

It will be noticed from the tables that the only items that were found to vary with the amount of electricity actually sold from a given plant, were coal stores, water and repairs. Should any managers find that their wages or other costs vary also on this account, it is easy to separate these into stand-

ing-by and running costs by the above simple method of differences. Perhaps it may be well to remind those members who did not read the author's paper on the "Cost of Electricity Supply," in England. last year, that this method of analysis by differences is a means for determining the cost the station is put to in having to supply every additional kilowatt hour from its plant, and it consists in dividing the difference between the amounts debited in the six winter and six summer months, respectively, to the special account required to be so analyzed by the difference in the number of kilowatt hours sold in these two respective periods, the result giving a very correct estimate of the running cost per kilowatt hour during that year.

In the comparison of the cost of an electric lamp with that of gas, it has been assumed that the gas is of a quality known as sixteen candles, which, burnt with ordinary burners, generally gives two candle-power per cubic foot.

In order to make the comparison, in Columns 8, 9, 10, of Table II., between the charges for electricity and gas, applicable to other towns, it seems to the author fair to assume that the ratio of the cost of producing gas and electricity in any one town bears generally a constant ratio, as the items which affect this, such as the cost of capital, coal, labor, etc., would generally vary in similar proportions.

From Table II. it will be seen that, even in the year 1893, when something under 300,000 kilowatt hours were sold, the charges for a sixteen-candle-power lamp, burning four hours a day throughout the year, would have been less than gas at 80 cents per 1,000 feet, and that last year, when the supply was under 1,500,000 kilowatt hours, electricity burnt under these circumstances could compete with gas at 50 cents; while for street lamps, or lamps used in basements all day long, electricity was cheaper than gas at $1 per 1,000 feet, in 1887, supplied from the small pioneering station.

Columns 11 and 12, of Table II., giving the charges for current and total inclusive cost for a 500-watt arc lamp, may be of interest, as also may be the proper tariff for motive power, shown in Columns 13 and 14 of the same table.

To illustrate how impossible it is for electricity to be supplied on a uniform tariff at so low a price to the lamps used in the average house of the middle classes as it can be profitably done on an equitable sliding scale, it is only necessary to note that to have produced the same amount of profit in 1896 the uniform charge per kilowatt hour would have been to this four-hour class of consumer 9.3 cents against the equivalent charge of 7.5 cents, or at an increased charge of 25 per cent.

If we take the case of saloons and clubs, which keep open late throughout the year, and burn, on the average, their lamps six hours a day, the necessary uniform charge would have been 46 per cent. higher, and, in the case of basement users, using their lamps ten hours a day, on the average, throughout the year, a uniform charge would have to have been 70 per cent. dearer than it could have been supplied on the system of equal profits, whereas the one-hour consumer, on the uniform system, would have been charged 9.3 cents against the proper charge of 17.86 cents per kilowatt hour, and, as 15 cents would have been the actual cost to the supply station in giving him this kilowatt hour, the company would have lost no less than six cents for every kilowatt hour so sold.

It may be thought that the amount of the service rentals shown in Column 8, of Table I., to be equitable in the different years, may prevent the classes the author so strongly suggests should be catered for from being able to benefit in point of economy by a supply; but it is easy to show from the tables that even in the year 1894, with a sale of 583,701 kilowatt hours in any ordinary residence where at least four lamps are generally used till 10 p. m., any householder should have been able to get electricity cheaper than gas. Moreover, directly cheaper forms of electricity meters are put on the market, and meter readings can be taken once a quarter instead of once a month, as hitherto, these service rentals will very much diminish.

In case any of the members should be inclined to think that there is no necessity to depart from the ordinary method of charging a uniform price per lamp hour, the author has prepared the curves showing how very slightly the total costs of a central supply company vary in the different months of the year, notwithstanding the enormous variation in the number of kilowatt hours sold. These curves, Fig. 1, in the author's opinion, are the most speaking condemnation any manager can possibly have of the commercial unsoundness of the uniform method of charging.

In order to demonstrate very clearly the effect of the gradual development of the business on an equitable sliding scale of charges, the author has prepared the curves, Fig. 2, showing how the varying charge per kilowatt hour, according to the number of hours the demand is used, has diminished in the various years, as many managers have suggested that this necessity for a high initial rate will disappear on electricity being more generally used.

THE DAYLIGHT WORK OF CENTRAL STATIONS.[1]

BY T. C. MARTIN.

THE development of the central station industry has been in some respects, a disappointment. We have now had nearly twenty years of central station work in this country, and have witnessed an enormous growth in that period within the field of work covered by this organization, but it is apparently as true to-day as when the association was formed, that the companies restrict themselves injuriously in their natural and logical advance by remaining mere lighting corporations. What would happen to us all if some new lighting medium came into vogue that deprived us of our illuminating business entirely? If we had to fall back on daylight work, might we not be better off?

A brief retrospect will not be out of place, if followed by a study of the present situation. It is as well not to go back further than 1886, for, although arc lighting is a full decade older than that, the industry ten years ago took its great leap forward. A careful investigation shows that, in 1886, there were about 410 central stations in this country. Of these, only 300 furnish available statistics, and it would appear that 226 of the companies were then only doing a night arc lighting business. It is safe to assume that all the companies which did not report were in the same category as the 226; so that, out of the 410 local companies, some 325 were doing business only between dusk and daylight, and were standing idle all the rest of the time. In other words, taking the year through, they were idle nearly two-thirds of the day, if the average running be taken at 3,000 hours a year.

To what degree have these conditions been improved in the ten years? This is an extremely difficult question to answer, but a few tentative figures may be acceptable as a basis for study and discussion. At the close of 1896 there were about 2,400 central stations in operation in this country, so that in ten years the number had increased sixfold, a gain that is simply stupendous. Of these 2,400, however, 975 had, from the figures obtainable, no day circuits, and 220 others had only arc apparatus, so that 1,195 local companies, by their own admission, were limited to night work. The case is not, however, so encouraging as might be implied from these figures. Of the remaining 1,200 companies, only 327 report day circuits, and if it is safe to assume that half of the 900 companies and plants not giving these details were without day circuits, it would appear that, out of 2,400 local plants, at least 1,500 are limited to the night hours for their earning capacity. It must be noted, however, that nearly all the 900 companies not specifying day circuits are operating incandescent circuits, very largely with the alternating current, so that the means for day operation are generally there under more or less favorable conditions.

It is obvious at once that an immense amount of capital and machinery is standing idle that might otherwise be productive of profit and dividends. Of the 1,200 companies confessing that they have no day circuits, only some 780 give their figures of capital and generating capacity in steam or water. It would appear that these plants, with a moderate capitalization of $46,908,000, and with an engine and water wheel capacity of 164,000 horse-power, are standing idle two-thirds of the day and often a great deal longer.

Such figures are given broadly, and may be a little inaccurate in precise detail, but it is the mere fact that is so striking. It is obvious that these figures apply to the great bulk of small stations. And yet some of them are certainly not small. At least sixty-five or seventy of them have each a capacity of 500 horse-power and upward, and several of them are legitimately capitalized at above a million dollars each. A company of such size ten years ago was rare and exceptional, and would have been difficult to start, except on the general hypothesis that its business would include something beyond simple street illumination, with a little house lighting thrown in. It may be doubted whether capital of any magnitude could be enlisted to-day for a company that had no ideas beyond ordinary lighting work.

If the stationary motor work, whose claims I ventured to urge on this association eleven years ago, had been left to the local lighting companies, I fear it would not have made much headway. The 327 and other companies with day circuits do an enormous amount of power work, but a careful analysis of somewhat incomplete data would lead one to believe that the isolated plants are the real backbone of the electric power industry to-day. Why this should be so, it is difficult to explain, except on the hypothesis that station current, when obtainable, often costs too much, and is generally not obtainable. It will, I trust, be understood that this paper is not offered in any wise as a criticism of central station management, but simply a presentation of the puzzling facts that confront students of the situation. No one can know the inwardness of the problem so well as the central station manager himself, and no one can be more deeply interested than he in dealing with it wisely and well.

---

[1] Abstract of paper read before the National Electric Light Association, Niagara Falls, N. Y., June, 1897.

It might be said that, in a general survey, four new factors have presented themselves in the last ten years for the consideration and approval of the central station manager. These are motors, alternating-current supply, storage batteries and electric heating. The alternating current is, for most stations, still restricted to night work; and will be, probably, until more single-phase motors of successful character are on the market. This form of current has given such a tremendous stimulus to lighting that it deserves a wider range of usefulness, so that, in time, alternating-current stations may compete with direct-current stations as earners of dividend.

Allusion has already been made incidentally to motor work. What is possible in this direction is best judged from what the large stations do. Of course, this is in some respects an erroneous guide, but in the same manner as great men are exemplars for those of less heroic bulk, so the large stations indicate the actual possibilities, even for a lower plane of execution. The following are figures of a large western central station, showing the horse-power of motors connected to the circuits, and the percentage that the power consumption bears to the total output. The data come down to March 31, 1897.

Low Tension.

Power connected April 24, 1897...........	6,962	horse-power
Power p. c. of the total switchboard output	22.8	per cent.

High Tension.

500-volt power connected April 24, 1897....	1,566	horse-power
Power per cent. of high tension output....	21.4	per cent.

All Systems.

Power connected April 24, 1897	6,962	horse-power
Power p. c .of the total switchboard output	22.8	per cent.

Another example is to be found nearer home, in the work of the New York Edison Company. The motors to which that company supplied current from its distributing mains represented, on January 1, 1896, a total installation of 11,640 horse-power. On January 1, 1897, the motors connected were the equivalent of 15,930 horse-power, an increase of motors connected in a single year of 4,290 horse-power, or 36 per cent. This does not include an installation equivalent to 1,142 horse-power in motors, to which current is supplied from the New York Edison stations during minimum hours, or for emergency and breakdown connections. It will be seen that this brings the total horse-power in motors connected to the company's mains up to 17,072 horse-power. The average size of these motors is from three and one-half to four horse-power. Of the total motors connected it is estimated that about 5,000 horse-power, equivalent, is installed in connection with direct electric elevators and grip hoists.

In order that the idea should not go abroad that the big companies are monopolizing the power business, but that it is open to all, I would mention that in Massachusetts, where there is only one large city, no fewer than eight companies out of fifty-eight are supplying power from their arc circuits; eighteen from incandescent circuits, and twenty-nine from independent power circuits; the total being about 14,000 horse-power of motors on the circuits. The asking rate for kilowatt hour averages about 20 cents, but runs down as low as 10 cents.

Turning next to storage batteries, it is not my intention to agitate old discussions, but simply to give a few figures, which would go to show that the batteries may do more than perform the Alpine feat of taking care of the peak of the load. There are at the present time in America—I blush to give the figures—only fifteen central stations using batteries, with a total capacity of 25,000 horse-power hours' output. Four other stations are being equipped. I hope devoutly that some future chronicler will be able to report that 1,500 stations are equipped with batteries, and that by their reservoir capacity they have answered in the affirmative the question whether their life was worth living. What batteries can do is best exemplified by the Duane street station of the New York Edison Company, one of the biggest stations in the world, with an engine and generator capacity of 20,000 horse-power. The load during minimum hours, I am told by Mr. J. W. Lieb, Jr., the general manager of the company, is such that it can be supplied in that period from the storage battery annex at the Bowling Green Building in the southern tip of the tongue of Manhattan Island; or from the storage battery plant at the Twelfth street station, either alone or in conjunction with current supplied from the Twenty-sixth street station over the feeder tie lines. The supply of stored current from the batteries in the annex stations during the minimum hours enables the big Duane street station to be shut down every night from 10:30 p. m. to 5 a. m.—nearly seven hours; and on Sunday the operation of the generating machinery at Duane street is limited to one watch. I do not hold a brief for storage batteries, but in view of such facts it is hardly possible to do other than press their claims on the attention of central station managers.

A word in conclusion as to electric heating. It is said that, with current sold on the basis of 20 cents a kilowatt hour, no business can be done in heating, and that, even if the price be cut in two, the inducement to possible customers is not great. If this were true, the matter of price of current might forbid the operation of a single fan motor from central stations. Making a rough calculation of 1 cent per hour for the ordinary fan motor;that is, 10 cents a day for ten hours steady running, or, say, $3 per month, or $36 a year. Allowing twelve such motors to the horse-power, the local companies are selling current to thousands of willing customers in the summer time at the rate of $430 a year per horse-power, for a working day of only ten hours. Other quotations can be made showing the high price got readily for current in small quantities from purchasers who are perfectly satisfied with the bargain, and find it pays them also very handsomely in some element of comfort, pleasure, convenience or even economy.

A test taken three years ago, for twelve weeks of current consumed in cooking a dinner of several dishes daily for a large number of persons, showed that for ninety-seven persons the current fell as low as 307 watt hours per person. This would make 29,779 watt hours, or, in round figures, thirty kilowatt hours. At 10 cents per kilowatt hour, that means an expense of $3 per day, or, say, $90 per month. It will, of course, be objected that, in a great many isolated plants, the current made on the spot does not cost to exceed 5 cents per kilowatt hour, which would, in the building where the test was made, have brought the sum down to $45. I have tried to get some basis of comparison between this and an equal amount of work on a gas stove or range, for an equal number of persons, but it is not easy to obtain. In one family I know, which consists of six persons, they have been cooking by gas for some five years. It costs, with gas at $1.25 per 1,000 cubic feet, on an average, $5 to $6 per month, or from 16 to 20 cents per day, or about 3½ cents per head per day, if all are at home to every one of the three daily meals, which is far from being the case. If the same expense averaged for the ninety-seven persons for three meals daily, the outlay for gas in cooking would be between $90 and $100 a month, or about as much, if my figures are approximately right, as electricity would cost, if the current were supplied at 5 cents per kilowatt hour. This is certainly a very encouraging showing for electricity, but we must not forget that central stations do not exhibit much anxiety to sell their current at 5 cents per kilowatt hour, or even per horse-power hour, and this is one reason why isolated plants have multiplied so tremendously in our cities. I might add, as one point of interest, that, when the family I mention began to cook with gas, it bought a gas range for $25 and paid $2 or $3 more to get it set. The range has worn out, and the family is now hiring a good one from the local gas company for $3 a year.

From these crude remarks of mine, it will be seen how sadly tentative and experimental the art of electric cooking is for most of us; but is it not the duty of the local lighting companies to go into this matter and see how far they can foster the new art, by introducing the apparatus and furnishing current for it cheaply? Even if the price falls short of $430 per horse-power per year, for ten hours a day only, they should not feel discouraged.

I have spoken of cooking, but this is but one of many fields of usefulness for electric current heating supply. Our esteemed ex-president, Mr. J. I. Ayer, who has placed at my disposal much interesting data that I cannot produce here, for lack of time, gives me also a variety of information as to work that has lately fallen within his sphere of practical attention as representative of a large electric heating company. Their work includes a wide extent of shoemaking machinery, heated silk-finishing rolls, leather-working machinery, 387 curling-iron sets in the dressing rooms of the combined Waldorf and Astoria hotels, in New York City, seventy-two sets in the Parker House, Boston, and apparatus in the Plankinton and Pfister hotels, Milwaukee, as well as on the American line steamers across the Atlantic. It would not be fair to omit the 14,000 car heaters installed, of one make alone, in the past year and a half. A blankbook manufacturer has had in use since 1894 from thirty-five to forty electric glue pots, and Duryea & Co., the starch makers, are also users of electric heat apparatus. In Knabe & Co.'s piano factory, at Baltimore, twenty electric heaters have recently been placed; and there is a long list of clothing houses throughout the country that use electric irons. The same is true of vulcanizers for bicycle tire agencies and factories, while irons in large numbers have been supplied to State asylums in Indiana, Michigan, Wisconsin, Illinois, New York, Massachusetts, Maine and Maryland. It is simply impossible that all this apparatus should have been put in, unless it was economically or practically worth while; and this being so, is not the electric heat field one in which the local companies can now begin to work with advantage? Surely, here lies opportunity of the largest kind, to help the introduction of apparatus that must serve as a large customer for current at all seasons of the year.

RECENT PROGRESS IN ARC LIGHTING.*—I.

BY PROF. ELIHU THOMSON.

We have, to-day, in actual commercial use arc lamps running under quite a variety of conditions as to nature of current, regulation of the current, and conditions concerning the arc itself as a source of light.

According to the manner in which the arc lights are worked on an electric circuit, we are enabled to make several general divisions, about as follows:

Series arcs on
- Constant, continuous-current circuits.
- Constant, pulsating-current circuits.
- Constant-potential, continuous-current circuits.
- Constant, alternating-current circuits.

Single arcs on
- Branch of constant-potential, continuous-current circuit.
- Branch of constant-potential, alternating-current circuit.
- Compensators with alternating current.
- Constant-current transformers.

It will, at this time, be scarcely necessary to dwell upon the main features of several of the cases above enumerated, as they are too well known to call for comment here. Thus, the case of arcs in series upon a continuous, constant-current circuit is the oldest and best known. It has the peculiar merit of permitting economical transmission by currents of potentials of several thousand volts; gives ease of regulation and great simplicity of circuits and connections, and does not demand the highest grades of carbons for the open arcs. On account of the relatively higher potential demanded by an inclosed arc, or a partially inclosed arc, and the consequent restriction of the number of lights in a series with a given permissible voltage, there has naturally resulted thus far very little real commercial use of series inclosed arcs, and where they have been on trial use they have, in most cases, so far as the writer is aware, been discontinued.

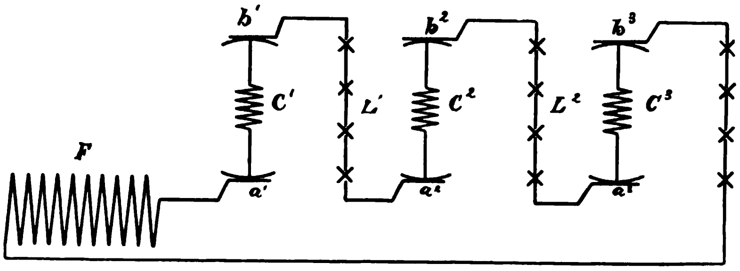

FIG. 1.

In recent years the tendency in series arc lighting with constant current has been to increase of voltage of the dynamo, and machines capable of working 125 to 150 arc lights in a series have been developed successfully. But the potential between terminals in such a case may be 7,000 volts—often too high for security, and in some places forbidden by special legislation. An ingenious method of employing such machines when, as is the case with the Brush machine, several commutators are present in series relation, has been devised by Mr. Green, of the Brush Company. This plan demands that separate pairs of wires be run from the machine to the switchboard for each circuit, but the unquestionable effect of the new connections is to limit the difference of potential which is possible to be manifested between any two parts of the circuit through the machine and lamps. A simple diagram, like Fig. 1, will make the connection and its general effect on the distribution of potentials clear to those who may not have given attention to the subject. Let F be the field circuit of the dynamo; we may for simplicity, neglect its resistance and that of the wire of the circuit. If C^1, C^4 and C^3 represent the sections of armature conductor, and L^1, L^2, L^3 the series of lights connected between the commutators of the machine, it will be seen that each armature section, C^1, C^2, C^3, with its appropriate commutator, acts to produce a difference of potential, which may be represented by the vertical a^1, $b^1 = a^2$, b^2, and a^3 b^3, while the fall of potential through each series of lights, L^1, L^2, L^3, results in bringing the line potential down, as it were, for another raising. In such a system, evenly loaded, the highest difference of potential anywhere to be found will evidently be that required to run a series of lights looped between two successive commutators. If lights are cut off from any set or loop, the potential difference between the terminals of that loop falls accordingly without any corresponding or proportional rise between any other parts of the circuit. If, however, lights are cut off one set and added to another, so as to keep the machine in full work with unbalanced loads, then the potential distribution is, of course, disturbed, and the system approaches the condition of all commutators connected directly in series, and the lights all in one series—the old plan.

The immediate future of the series arc lighting system appears to be in the development of large dynamos, up to, say, 300 arc lights each, running at such speeds that one or a pair may be easily coupled directly to the shaft of a moderately high speed engine.

While it is true that in the open coil types of dynamos—such as the Brush and Thomson-Houston—the current, as set up by the armature, must necessarily be wavy, still it must be borne in mind that the field magnet coils, the line and the series lamp magnets have, together, a considerable inductance, the effect of which is to smooth out the minor fluctuations, so that the current becomes fairly uniform. A slight tremor in the current, with differential magnet lamps, is an assistance in preventing tardy feeding. In the pure shunt type of lamp, this is of less effect on the feed.

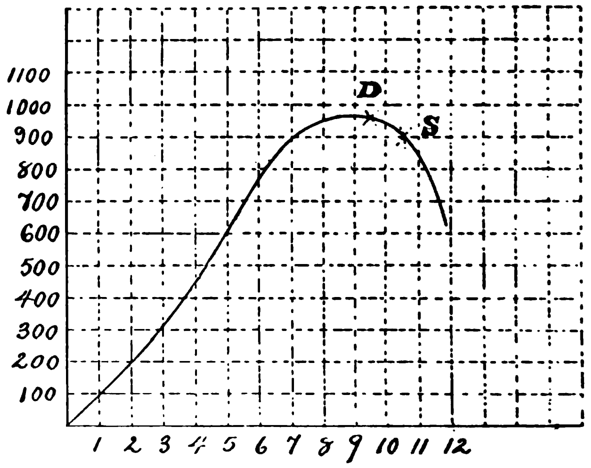

FIG. 2.

It has been thought by many that arc lamps are interchangeable (if made or adjusted for the same current) from the circuit of one type of series arc dynamo to that of another, without difficulty. In a general way this is true, but not by any means necessarily true. Also, it may happen that a dynamo which will take a certain load of differential lamps at a certain strength of line current, can only work with satisfaction on pure shunt lamps with a 10 per cent. to 20 per cent. increase of line current, and fewer lamps in series. In this case the differentials secure a stable current when working on a part of the characteristic curve back of that were the heavy droop occurs, D, Fig. 2, while the shunt lamps are only given stable current at S. Instability or quick rise and fall with flashing and possible intermittent extinguishment otherwise result.

On the other hand, any circuit of pure shunt-feed lamps will take differentials adjusted for the same current without difficulty. But in such case, if the current fluctuates in value and there be but few differential lamps on the circuit, with a large proportion of the shunt-feeding type, the differentials are the ones to suffer and not the others. The former are sensitive to current variations, the latter indifferent thereto.

---

*Read before the N. E. L. A. Abstract.

There is neither time nor space to devote to the details of arc lamp mechanism for constant-current circuits, though much might be said in regard to the proportions that should be given to the parts, the character of pull to be secured in the magnets controlling the lamp, the securing in clutch lamps of a slow or "sneak" feed (as it is sometimes expressively, if not elegantly, termed) for the carbons, the cut-out switch, etc., in both differential and shunt-magnet-control mechanism. There are two points, however, which may be touched upon in this connection, as tending to secure the best results. First, the variation of pull for a given variation of current in the magnets controlling the lamp should be as great as possible. Second, there should be as little as possible variation in the force required to feed or recover from feeding. The force required to be imparted to the mechanism to release the clutch, detent or escapement should be as little as possible, and but a very small fraction of the total magnetic force in a differential or shunt-feeding system. Otherwise, the lamp will not be a sensitive feeder. Lamps are frequently found which form their arcs well enough, but hang up or delay at the feeding point, the action of feeding being preceded by quite a rise of potential between the carbons at the arc. This is owing to too much force being required to unclutch or release the mechanism. A good lamp should feed on a variation of three to five volts, and, with certain constructions, a feeding action within one-half to three-quarters of a volt variation for a 45-volt arc can be readily attained.

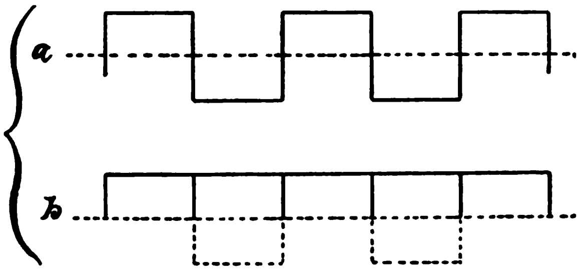

Fig. 3.

Passing now to the consideration of the use of pulsating currents in arc lighting, it may be said that at present little or nothing has been done commercially in the United States in the use of such currents. The subject becomes one of importance in connection with what are known as rectifiers. These are machines that take an alternating current and commute the waves, or rectify them, so that the flow of current is in the same direction always, though rising from zero to a maximum for every alternation in an alternating current. The more or less near approach to continuity of current will depend upon the shape of the wave rectified. A rectangular wave, properly rectified, would, as in Fig. 3, give a true continuous current. Other forms of wave give less continuity, depending on the sharpness of the individual wave peaks, c, d, Fig. 4. The character of arc produced by the rectified current resembles closely that of the continuous-current arc, in that the crater in the positive carbon is present, and the negative tends to point itself. There is, however, a strong note or sound evolved from the arc, depending for its pitch upon the periodicity or frequency of the alternating current. The inductional effects of the pulsating currents in lines upon neighboring lines will, of course, resemble those of alternating currents, though less musical than the latter when a sound results, as in a telephone. In order to make it easy to commute or rectify such a high potential of alternating current as would be needed to feed, say, a series of forty to fifty arc lamps with pulsating current, certain conditions are very desirable. One of these is that the current to be rectified should be of constant value, though alternating. The writer showed, nearly ten years ago, how a constant-current transformer could be made, using primary current at constant potential to obtain secondary constant current. When such a current is rectified, the same characters are preserved, and the regulation is all that could be desired for all loads within the capacity of the apparatus. The efficiency of transformation is also quite high, and the apparatus is not of excessive size for a given output.

The above relates to the rectification of a single-phase current. When, however, two-phase or three-phase currents are to be rectified, there will be at last two or three constant-current transformers, one for each phase, and the secondary current may be combined through commutators resembling those of the Brush arc dynamo for the two-phase, and the Thomson-Houston for the three-phase. In such cases the resulting rectified current is much more nearly a steady or smooth current, and not so much of a pulsating character. This is, of course, owing to the relation of the phases being such as to cover each other's zeros or to overlap. Under proper working conditions there should be a certain field for the use of rectifiers in the United States, as well as in England, where Ferranti has for some time past had some of them in use. It is difficult to adapt a rectifier to periodicities of as high as 125 per second, but with sixty periods the problem is comparatively easy. The use of rectifiers has the one great advantage of permitting the generation of current in a station to be by means of large direct-connected dynamos, a portion of the output of which is used in the ordinary way to feed lights, etc., through the usual constant-potential transformers, while another portion, feeding rectifiers, supplies the arc lamps of the system instead of special arc dynamos, while, if needed, the whole capacity of the generator may be utilized for one or other kind of load, as desired.

The arc lamps worked by rectifiers are like continuous-current arcs in giving the downward distribution of light from the positive crater, a feature of great value in street lighting. There is also complete regulation—such that lights may be cut out ad libitum by shunting, while the other lights remain unaffected. Furthermore, the efficiency of the rectifier is high, and may easily be made over 90 per cent.

The inevitable use of a choking resistance in series, with arc lamps run from constant-potential lines, is now pretty generally understood. Without it the current in the lamp branch is unstable, owing to the fact that the resistance of an arc is not a definite quantity, but varies for a definite length of arc in inverse ratio to the current flowing, or even falls more rapidly than the current increases, or vice versa.

Much was said, and some considerable amount written, a few years ago about lamps in series on constant potential robbing each other, so that when one was bright the other was dim, and the reverse. This phenomenon does not occur with properly constructed lamps, which are sufficiently sensitive feeders.

The distribution of current for arc lighting at constant potentials has undoubted advantages, one of which is the relatively low tension and absence of danger. Another is the facility of installation along with incandescent lights, and ease in metering the supply. The loss of energy in the distribution may, at full load of lines and moderate distances from the supply station, be, say, 10 per cent. or more, chargeable chiefly to feeder drop, and about 15 to 20 per cent. in dead resistance in the lamp branch. We may take, then, 25 per cent. as an average loss in reaching the lamps. This loss, which is much greater than the percentage of loss on the series system, is yet largely, if not wholly, made up by the superior efficiency of the constant-potential, low-pressure generators of large capacity over that of arc machines of relatively smaller output, and by the higher engine efficiency which may readily be attained in driving large generators, especially when working with economical loads. It must not be forgotten, however, that for equally good results a better and more expensive carbon will be required for constant-potential work than for plain series arc lighting. These observations relate, of course, to ordinary open arcs with full supply of air reaching the hot ends of the carbons. The conditions existing with long-burning lamps or inclosed arcs will be alluded to later.

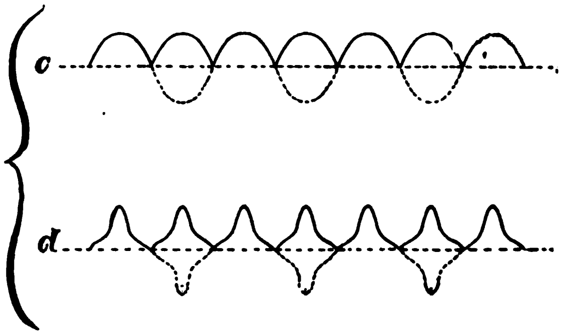

Fig. 4.

One serious objection to the arrangement of lamps in series between constant-potential mains, especially those of 220 to 500 volts, is the inflexibility, or inability, to cut off some lamps in a branch without substitution of equivalent resistance, which substitution, of course, means that the same watts are consumed whether the lights burn or not. With alternating current at constant potential there is greater flexibility, but, unfortunately, no alternating-current arc lamp is likely to equal in its effects lamps making use of continuous currents or unidirectional currents.

REPORT OF COMMITTEE ON DATA.[1]

BY F. R. LOW.

In your last report you submitted returns from eighty-one electric light stations using coal as fuel, showing the following results obtained in actual practice:

	Watt hours per lb. coal.	Lbs. coal per kw. hour.
Maximum	237	4.22
Minimum	33	30.3
Average	108	9.26

In your conclusions you called attention to the fact that, at the Chestnut Hill pumping station at Boston, an effective horse-power had been developed on 1.34 pounds of coal per hour. If a steam dynamo can be constructed and operated as efficiently as was this steam pump, it will deliver 746 ÷ 1.34 = 557 watt hours per pound of coal and require only 1,000 ÷ 557 = 1.8 pounds of coal per kilowatt hour.

I am asked to account for this difference between the actual efficiency attained in the every-day practice of electrical stations and the efficiency apparently attainable in other applications of power.

In the first place, the standard which you have set is, purposely, no doubt, extremely high. The Chestnut Hill engine holds the world's record for steam efficiency, having developed an indicated horse-power on a consumption of 11.22 pounds of steam per hour, and embodies all the refinements of modern engineering. There is no reason why an equally efficient engine cannot be built and attached to a dynamo, should it appear advisable to incur the expense of all this refinement for the attainable difference in expense of maintenance.

There are steam dynamos now running on thirteen pounds of steam per indicated horse-power, which, with a difference of fifteen per cent. between the indicated and electrical horse-power, and an evaporation of ten pounds of water per pound of coal, would require $\frac{13 \times 1{,}000}{.85 \times 746 \times 10} = 2$ (prox.) pounds of coal per kilowatt hour, and deliver 500 watt hours per pound of coal; and these figures, actually attainable with existing steam dynamos for short periods under test conditions, are what should be compared with the record-making test of the pumping engine in your report.

Steam per horse-power hour.		Equivalent§ Coal per kilo-watt hours.	Equivalent Watt hours per lb. coal.
Indicated.	Effective.		
11.22	13.4*	1.8	557
13.	15.3†	2	500

*Calculated from water pumped against pressure.
†Electrical horse-power, 746 watts.
§Calculated on evaporation of 10 lbs. water per lb. coal.

Thus reduced, the question becomes one of accounting for the difference between results obtained by a high-class engine, running under test conditions, and those obtained by an entire station, under running conditions involving not only the decreased efficiency of the units under unfavorable load conditions, but all the standing losses of the station, inferior fuel, etc. The difference will be made up mainly from the following items: 1. Decreased boiler efficiency. 2. Lesser normal efficiency of engine. 3. Impaired conditions of engines. 4. Unfavorable engine load. 5. Leakage. 6. Condensation. 7. Auxiliaries. 8. Heating.

Much has been said of the disadvantage under which electric light stations labor on account of the wide difference between the minimum and the maximum loads, and thermal storage has been suggested as a means of evading this loss of efficiency. It is quite possible that this loss has been overestimated, so far as the boilers are concerned.

The capacity of a boiler is determined by the amount of water which it will evaporate in a given time; its efficiency by the combustible required to evaporate a pound of water from and at 212°. To determine how the efficiency varied with the rate at which the boiler was run, within limits, I have plotted on Fig. 1 in the horizontal direction the water evaporated per hour per square foot of heating surface, and in the vertical direction the pounds of water evaporated from and at 212° per pound of combustible, as determined by 30 different tests on Babcock & Wilcox boilers. If there were any decided tendency for the efficiency to follow the rate of evaporation within the range there covered, it might be expected to show itself here, but it will be seen that practically as good results are obtained at over five pounds per square foot of heating surface as at 1.75 pounds, and the intermediate tests show no dependence on the rate of evaporation. In Fig. 2 I have plotted in the same way all the tests of which I could find a record, and in this wide range still no evidence is apparent of any dependence of the boilers represented on the rate of evaporation within the range covered. This means that the variation of efficiency of boilers within the range here comprised is less than the variations due to different firing, etc.

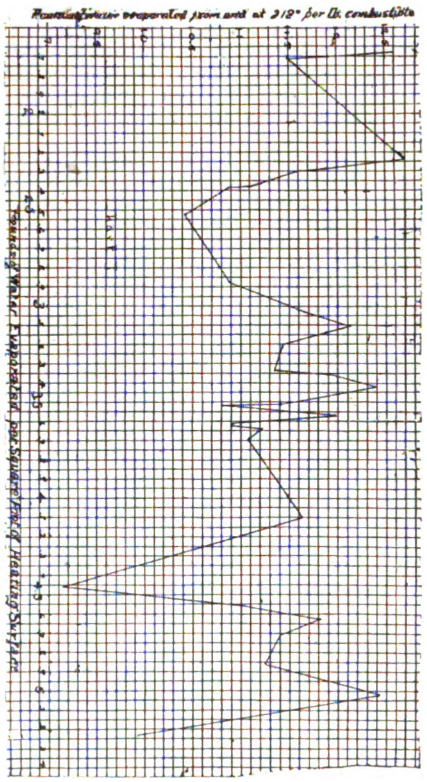

FIG. 1.

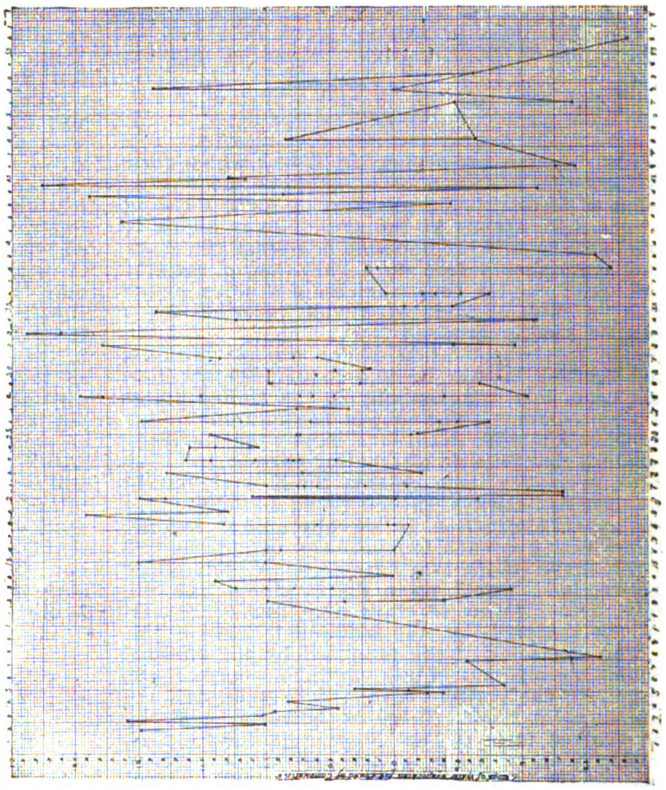

Fig. 2.

---

[1] Presented at the Niagara Meeting of the N. E. L. A.

Wm. H. Bryan, in a paper read before the Engineers' Club, of St. Louis, gives the data and tests on a battery of horizontal tubular boilers which were forced to nearly double their rated capacity with a decrease of only six per cent. in their efficiency, and which could, doubtless, have been diminished to one-third of their rated capacity with a less impairment still. In other words, with good management and an adaptation to condition, these boilers would have taken care of a maximum load six times the minimum without suffering extremely.

If a boiler runs sixteen hours a day at an average rate of twelve pounds of coal per square foot of grate per hour, and stands the other eight with a consumption of .5 of a pound per square foot of grate per hour, the coal used, while idle, will be 2.04 per cent. of the whole. If it runs half the time, the expense in coal, while standing, will be four per cent. of the total amount. The following table gives the percentages for different lengths of running and different rates of combustion:

Hours Running.	Hours Standing.	Percentage of Total Coal Used in Idle Boilers at .5 of a Pound per Square Foot of Grate While Idle. Average Rate Combustion per Square Foot Grate While Running.				
		12	15	18	20	24
23	1	.18	.15	.12	.11	.10
22	2	.38	.30	.25	.23	.19
21	3	.59	.47	.40	.36	.28
20	4	.83	.66	.55	.50	.41
19	5	1.08	.87	.66	.65	.55
18	6	1.37	1.10	.92	.83	.69
17	7	1.69	1.35	1.13	1.02	.85
16	8	2.04	1.63	1.37	1.23	1.03
15	9	2.44	1.92	1.64	1.48	1.23
14	10	2.89	2.33	1.99	1.75	1.44
13	11	3.40	2.73	2.30	2.07	1.70
12	12	4.00	3.23	2.70	2.44	2.04
11	13	4.69	3.79	3.18	2.87	2.40
10	14	5.51	4.46	3.75	3.38	2.83
9	15	6.50	5.26	4.42	4.00	3.35
8	16	7.69	6.25	5.26	4.76	3.85
7	17	9.19	7.41	5.96	5.79	4.87
6	18	11.11	9.09	7.69	6.98	5.88

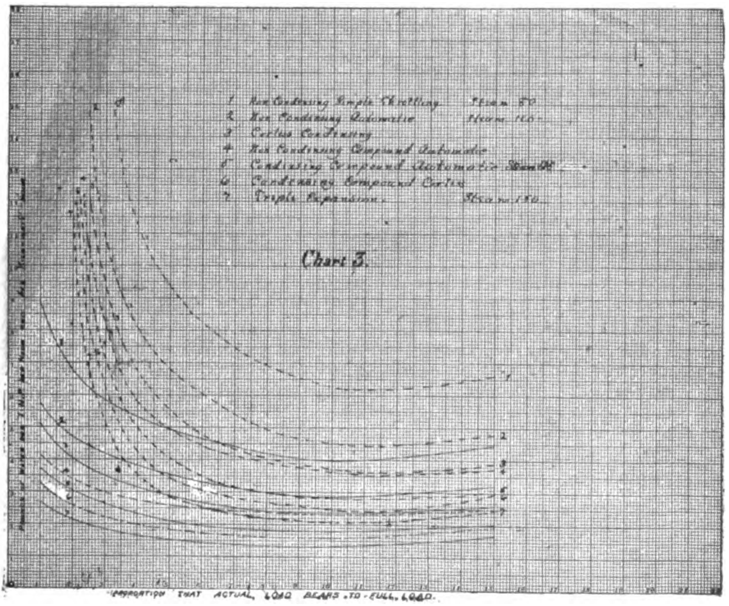

FIG. 3.

It has been a matter of surprise, in following out this investigation, to find so moderate a difference between the performance of the boilers reported for long periods under widely varying capacities, and charged with all the coal used for banking, etc., and their normal efficiency under test conditions. The ratio in 14 cases varied 84 and 97 per cent. comparing the actual with the best duty demands special consideration, for it affects directly the whole efficiency. Inefficiency in an engine affects only the steam which it uses, but inefficiency in a boiler affects the cost of all the steam produced for all purposes.

Engine Losses Due to Unfavorable Load.—The performance that we have taken as a standard was accomplished at the load for which the engine was particularly adapted. The performance that we are comparing with it was accomplished under all sorts of conditions of over and under-loading. Fig. 3 is given by Prof. R. C. Carpenter[3] as showing the rate of steam consumption that may be expected with engines of different types, and the method of variation of that rate with change of load.

These curves are based upon the steam consumption per indicated horse-power, but what we wish to know, not only for the purpose of comparison, but in order to handle the units of a station intelligently, is the rate of variation per kilowatt hour.

That the curve will be different from the indicated horse-power curve, is shown by Fig. 4. The lower curve is the first curve of Fig. 3 re-drawn to a higher vertical scale. Assuming a difference at the best efficiency of fifteen per cent. between the indicated and electrical horse-power, I have laid out the upper curve, showing the rate of variation on the same engine per kilowatt hour. At one hundred horse-power the engine takes forty pounds of steam per hour per indicated horse-power, or 40 x 100 = 4,000 pounds per hour. But we only get eighty-five electrical horse-power out of it, so the cost per electrical horse-power is

$$\frac{40 \times 1{,}000}{85} = 47 \text{ pounds,}$$

and the cost per kilowatt hour,

$$\frac{40 \times 100 \times 1{,}000}{85 \times 746} = 63 \text{ pounds.}$$

Calculating the other loads in the same way, the points for the upper curve were located. This curve is brought down to its dotted position for ready comparison with the other. Owing to the increasing proportion of the frictional and electrical losses, the curve rises very rapidly with an under-load, while, as the load is increased, the diminishing ratio of these losses carries the point of minimum consumption further out, and it is seen that, while the steam rate per indicated horse-power is least at one hundred, the steam rate per kilowatt hour is least when the indicated horse-power is ten per cent. greater, and the line rises less abruptly as the overload increases. It would seem as though every station manager would know the most efficient rate of output for each of his units, and how badly they suffered from a departure from this rate, but I found this to be in no wise the case.

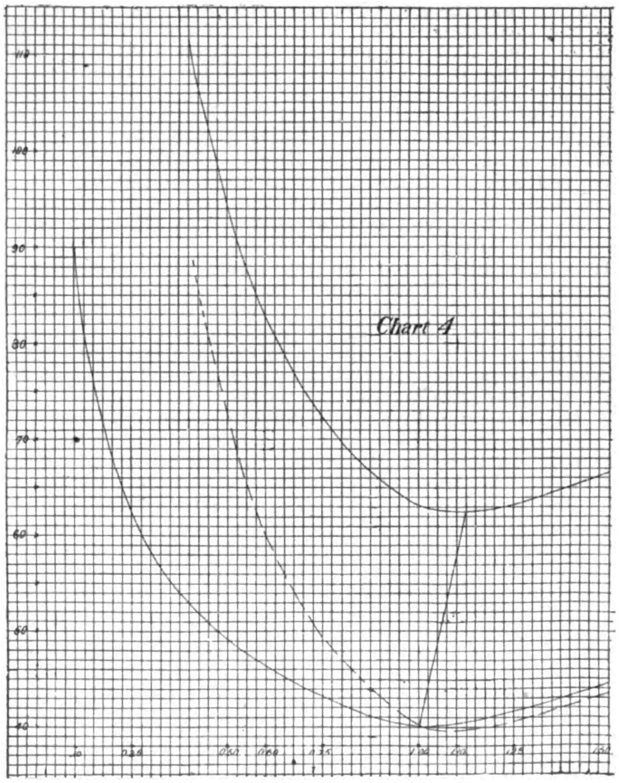

FIG. 4.

The station that has a constantly changing load is at the worst disadvantage from inadaptability of units. The "load factor" proposed by Crompton, expressed by the ratio of the area within the load-line to the area of the containing rectangle, is not a fair expression for this disadvantage; for of two stations, each having a "load factor" of sixty, for example, and one running six-tenths of the time on uniform load, as in Fig. 5, and the other all the time on a constantly changing load, as in Fig. 6, the first will be at a decided advantage in this respect. Its units, if adapted to their output, can be run at their maximum efficiency, and the station is better off even than a cotton mill, or other factory with a steady load, for it has a long run without interruption. It is to the fact that its load-line approximates more nearly this condition that the exceptional efficiency of the Brooklyn Edison No. 2 Station is due, and that an arc station is able to run at a less coal cost per unit of output. With a changing load like Fig. 6, however, the units are at their maximum efficiency only momentarily, as at A, B, C, D. By plotting the engine blocks into the actual load-line as they are plotted into this conventional line, and as they have been in the actual load-line submitted from the Brooklyn station, it can be determined how much and for what proportion of the time they were under or overloaded, and from one of the consumption curves for the given type of engine, the effect of such unfavorable loading may be estimated.

It is quite likely that the importance of the impairment of efficiency from this cause has been overestimated. Even on the steep kilowatt curve of the least efficient engine in Fig. 4 it will be seen that if all the engines in the station run all the time at half load, the impairment would be less than thirty-three per cent., and if they ran all the time at fifty per cent. overload, the impairment would be only eight per cent.

A. G. Pierce and R. S. Hale, who have made a careful study of the Boston stations of the Edison companies, say: "In our test we have finally found the variation due to causes which we first thought negligible, to be more than the variation due to change in load. As a matter of fact, the steam per indicated horse-power in our two 200 units holds within twelve per cent. over a range from one-quarter up to full output."

Leakage.—It is probable that the loss by leakage is greater than is generally supposed, and when the steam supposed to have been consumed is determined by the water meter, leakage, either in the form of water or steam, counts against the engine. In a surface condensing plant, if there were no loss by blowing off or leakage, no water would have to be supplied to the system after it was once charged. As a matter of fact, a constant supply is necessary. At one of the stations visited the leaks were about 2,000 pounds per hour in the winter time, and in the summer, with one-half the engines, two-thirds the boilers and all the heaters shut off, they were about 500 pounds per hour; in another they were 3,500 pounds per hour.

Condensation.—All the water evaporated by the boilers does not reach the engine in the form of steam, considerable being condensed in the conducting pipe. In a test this is allowed for and only the dry steam charged to the engine. Recent experiments have shown that each square foot of bare pipe exposed under average conditions will condense .85 of a pound of steam per hour. It would take at this rate only fifteen square feet to consume a horse-power (i. e., thirteen pounds of steam).

Auxiliaries.—A large amount of steam is used by the auxiliary engines about a station. While it is true that the boiler feed pumps, for instance, develop little power as compared with that of the main engines which they supply, they are, as a rule, very extravagant in the use of steam. The same thing is true of the ordinary independent air and circulating-pump. There are also in many stations small engines used for operating automatic stokers, fans for artificial draft, coal-handling machinery, etc., the aggregate steam consumption reaching a very considerable figure. There is a movement in the direction of replacing steam-operated auxiliaries by those operated by electric motors, reducing the piping system to the utmost simplicity. At a cost of, say, twenty pounds of steam per indicated horse-power, and a loss of fifty per cent. in its electrical transmission and re-development, one would have, at the point of application, only forty pounds of steam per effective horse-power, against the seventy-five or 200 pounds required by the steam motors, displaced, to say nothing of the reduction to be expected in the radiation and leakage losses.

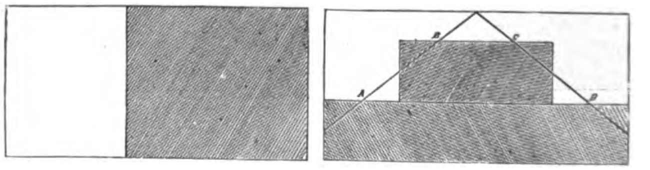
Heating.—The heating of the station usually follows from the unavoidable radiation, but the offices, and often considerable other space, are heated by exhaust steam at the expense of back pressure upon the engines, or by live steam from the boilers direct. Either of these, while necessary, is a drag on the efficiency of the station in kilowatt hours per pound of coal.

Starting Engines.—No inconsiderable amount of steam is used in getting a large engine ready to put to work and allowing it to "turn over" slowly for some time, as is often done before it gets its load. One manager assures me that a careful computation showed the cost of starting up a large engine, including the labor, oil, etc., as well as the steam required, to be over three dollars.

In the accompanying table, I have undertaken to show, for the few stations from which reliable data have been procurable, the proportions which the various demands upon the coal pile bear to each other and to the whole. The column headed "efficiency" shows the percentage of the coal actually used that would have been used by the standard equipment (10 pounds of steam per hour and the electrical horse-power .85 of the indicated). Under "engines" is the percentage of the total coal consumed by reason of the lesser efficiency of the engines; under "conversion," the percentage of the coal consumed by reason of the conversion losses exceeding the standard. The next three columns give the percentage of the total coal used to supply leakage, condensation and auxiliaries. The column under "boilers" gives the percentage by which the consumption was affected, by reason of the fact that the boilers evaporated more or less than ten pounds of water per pound of coal, while the column of "unassigned" gives the aggregate of all the losses not separately reported.

Station No. 1.—Incandescent, run 24 hours per day; average daily output, 13,600 kilowatt hours; coal per kilowatt hour, 8.3 pounds; watt hours per pound of coal, 120.5; boilers: water-tube; average evaporation per pound of coal, 8 pounds; average feed-water temperature, 212 degrees; average boiler pressure, 125 pounds; coal: buckwheat; engines: vertical, compound non-condensing, four-valve, direct-connected; water per hour per indicated horse-power, at best efficiency, 25.8 pounds; water per kilowatt hour, at best efficiency, 37.5 pounds; generators: General Electric.

Station No. 2.—Incandescent, run 6 to 12 hours per day; average daily output, 1,400 kilowatt hours; coal per kilowatt hours, 6.24 pounds; watt hours per pound of coal, 160.4; boilers: water-tube; average evaporation per pound of coal, 7.3; average feed-water temperature, 212; average boiler pressure, 125 pounds; coal: buckwheat; engines: horizontal, cross-compound condensing, high-speed, single-valve, automatic, belted to generators; water per hour per indicated horse-power, at best efficiency, 25.7; water per kilowatt hour, at best efficiency, 39.3; generators: General Electric.



Figs. 5 and 6.

Station No. 3.—Incandescent, run 24 hours per day; coal per kilowatt hour, 3.71; watt hours per pound of coal, 269.5; boilers, water-tube; average evaporation per pound of coal, 8 pounds; engines, vertical, compound condensing, four-valve direct-connected; water per hour per indicated horse-power, at best efficiency, 15.5; generators, General Electric.

Station No. 4.—Incandescent, run 24 hours per day; average daily output, 200,000 kilowatt hours; coal per kilowatt hour, 4.56 pounds; watt hours per pound of coal, 219.7; boilers, water-tube; average evaporation per pound of coal, 7.5 pounds; average boiler pressure, 160 pounds; coal, New River and hard screenings; engines, vertical, triple-expansion, four-valve, direct-connected; water per hour per indicated horse-power, at best efficiency, 15; water per kilowatt hour, at best efficiency, 23.5; generators, General Electric.

Station No. 5.—Arc and incandescent, run 24 hours per day; average daily output, 15,600 kilowatt hours; coal per kilowatt hour, 8.69 pounds; watt hours per pound of coal, 115.1; boilers; return tubular; average evaporation per pound of coal, 9.96; average feed-water temperature, 208; average boiler pressure, 125 pounds; coal, Bituminous, 2 parts; screenings, 1 part; engines, simple non-condensing, belted to generators; compound non-condensing, belted to generators; water per hour per indicated horse-power, at best efficiency, 29.1; water per kilowatt hour, at best efficiency, 47.7; generators, General Electric, Thomson-Houston.

Station No. 6.—Incandescent, run 24 hours per day; average daily output, 6,500 kilowatt hours; coal per kilowatt hour, 3.82 pounds; watt hours per pound of coal, 262; boilers, return tubular; engines, compound condensing, four-valve, belted to countershaft; water per kilowatt hour, per indicated horse-power, 15.5.

Station No. 7.—Incandescent, run 24 hours per day; average daily output, 13,000 kilowatt hours; coal per kilowatt hour, 8.91 pounds; watt hours per pound of coal, 112.2; boilers, water-tube; average evaporation per pound of coal, 6.1; average feed-water temperature, 180; average boiler pressure, 135 pounds; coal, Anthracite pea; engines, simple non-condensing, belted to generators; compound non-condensing, belted to generators; water per hour per indicated horse-power, at best efficiency, 28; water per kilowatt hour, at best efficiency, 45; generators, bi-polar.

Station No. 8.—Arc and incandescent, run 14 to 20 hours per day, averaging 17; average daily out-put, 12,400 kilowatt hours; coal per kilowatt hour, 8.67; watt hours per pound of coal, 115.3; boilers, water-tube; average evaporation per pound of coal, 6 pounds; average boiler pressure, 160 pounds; coal, Kentucky slack; engines, cross-compound condensing, direct-connected; tandem compound, belted to generators; water per hour per indicated horse-power, at best efficiency, 28; water per kilowatt hour, at best efficiency, 45; generators, Westinghouse, General Electric and Wood.

Station No. 9.—Arc and incandescent, run 24 hours per day; average daily output, 2,700 kilowatt hours; coal per kilowatt hour, 6.64 pounds; watt hours per pound of coal, 150.6; boilers, horizontal, tubular and water-tube; average evaporation per pound of coal, 9.83; average feed-water temperature, 140; average boiler pressure, 120 pounds; coal, Clearfield and coal dust, one-half each; engines, single-acting, compound condensing, belted to generators; simple, automatic, high-speed, non-condensing, belted to generators; water per hour per indicated horse-power, at best efficiency, 28; water per kilowatt hour, at best efficiency, 53.27; generators, Westinghouse, Thomson-Houston and General Electric.

Station No. 10.—Arc and incandescent, run 24 hours per day; average daily output, 3,400 kilowatt hours; coal per kilowatt hour, 8.62 pounds; watt hours per pound of coal, 116; boilers, horizontal, tubular and water-tube; average evaporation per pound of coal, 9.85; average boiler pressure, 112 pounds; coal, bituminous, 4 parts; Yars screenings, 1 part; engines, compound condensing and simple non-condensing, belted to generators; water per hour per indicated horse-power, at best efficiency, 28.5 pounds; water per kilowatt hour, at best efficiency, 38.1.

Station No. 11.—Arc and incandescent, run 24 hours per day; average daily output, 4,000 kilowatt hours; coal per kilowatt hour, 10.13 pounds; watt hours per pound of coal, 98.7; boilers, horizontal, tubular and water-tube; average evaporation per pound of coal, 5.75 pounds; average feed water temperature, 212; average boiler pressure, 115; coal, screenings; engines, compound condensing, belted to generators; compound condensing, belted to countershaft; water per hour per indicated horse-power, at best efficiency, 22 pounds; water per kilowatt hour, at best efficiency.

Station No. 12.—Incandescent, run 24 hours per day; average daily output, 4,300 kilowatt hours; coal per kilowatt hour, 7.45 pounds; watt hours per pound of coal, 134.3; boilers, horizontal, tubular; average evaporation per pound of coal, 11.36 pounds; engines, four-valve, simple; single-acting, compound; single-acting, simple; water per hour per indicated horse-power, at best efficiency, 34.3 pounds.

Station No. 13.—Incandescent, run 12 hours per day; average daily output, 5,000 kilowatt hours; coal per kilowatt hour, 7.33 pounds; watt hours per pound of coal, 136.5; boilers, horizontal, tubular; engines, tandem compound, four-valve, condensing; water per hour per indicated horse-power, at best efficiency, 20 pounds.

Station No. 14.—Arc and incandescent, run 24 hours per day; average daily output, 124,000 kilowatt hours; coal per kilowatt hour, 5.68 pounds; watt hours per pound of coal, 176.2; boilers, horizontal, tubular; average evaporation per pound of coal, 9 pounds; average feed-water temperature, 120; average boiler pressure, 115 pounds; coal, Tennessee, run of mine; engines, Tandem compound condensing, belted to jackshaft; double tandem compound, non-condensing, belted to jackshaft; cross-compound, belted to generators; water per hour per indicated horse-power, at best efficiency, 17.5 pounds; water per kilowatt hour, at best efficiency, 26.65 pounds; generators, Thomson-Houston, Eddy, Wood and Detroit.

THE INDUCTION FACTOR, A NEW BASIS OF DYNAMO CALCULATION AND CLASSIFICATION.[1]—I.

BY PROFESSOR CHAS. A. CARUS-WILSON.

SECTION I.

If a dynamo has A conductors on the surface of the armature, N lines of force per pole and p pairs of poles connected in series, the torque in inch-pounds for C amperes passing through the dynamo can be written

$$t = 1.41\, p\, C\, A\, N\, 10^{-8} \qquad (1)$$

When N is a constant quantity, the only variable in this equation is C; so we can write

$$t = 1.41\, C\, M \qquad (2)$$

where M depends simply upon the number of conductors on the surface of the armature, the number of lines of force per pole and the number of pairs of poles connected in series, and can be expressed thus:

$$M = p\, A\, N\, 10^{-8} \qquad (3)$$

If the armature rotates uniformly at n revolutions per second, the induced volts can be written

$$e = p\, A\, N\, n\, 10^{-8} \qquad (4)$$

Thus $M = \frac{e}{n}$ and may be defined as the induced volts divided by the number of revolutions per second; we may call M the induction factor of the dynamo.

We must not suppose that, because M can be defined as the induced volts divided by the revolutions per second, it necessarily depends in any sense on the motion of the armature. Equation (3) shows that M depends only upon the number of conductors, the lines per pole and the number of pairs of poles connected in series, and this equation holds true if the armature is at rest, and does not in any way involve the speed.

The induction factor can be determined experimentally, either by observing the torque for a measured current, or the induced volts at a measured speed; the latter method is the most useful, as the necessary observations are so easily made.

Example 1. We wish to know the torque on the shaft of a direct-coupled generator when delivering a current of 300 amperes. We see by the tachometer that the speed is 400 revolutions per minute, while the voltmeter reads 120 volts on open circuit; dividing the volts by the revolutions per second, we at once find the induction factor to be 18, and the required torque 1.41 × 300 × 18, or 7,610 inch-pounds. Thus, by simple inspection of the tachometer and voltmeter, we can ascertain the forces acting in the machine for any given current in the armature.

If the voltmeter can be read only when a current is passing in the armature, we must, of course, make an allowance for the internal drop, since the value of e used in determining the induction factor is the true induced volts.

Example 2. We have to find the pull on the belt driving a railway generator, the pulley having a diameter of forty inches. The tachometer reads 440 revolutions per minute, while the voltmeter indicates 550 volts, the ammeter reading 400 amperes. Neglecting the internal drop, the induction factor appears to be seventy-five, so that the pull on the belt is given by 1.41 × 400 × 75 ÷ 20, or 2,110 pounds. If now the internal resistance were 0.0375 ohm, there would be an internal drop of fifteen volts, so that the true value of the induction factor would be seventy-seven, and the actual pull on the belt fifty-six pounds more than we had estimated. The pull thus calculated is, of course, that due to the current in the armature, and does not include that required to make up the core and friction losses.

---

[1] Read before the N. E. L. A.

SECTION II.

If for t we put T, where T is the force at the rim of a pulley of diameter d, equation (2) can be written

$$T = \frac{1}{\pi d} M C 10^7 \text{ dynes} \qquad (5)$$

where d is expressed in centimeters, T in terms of C. G. S. unit of force and C in amperes. If, now, the circumference of the pulley be 10^7 centimeters, i. e., if $\pi d = 10^7$ centimeters, we can express the force of the dynamo thus:

$$T = M\ C \text{ dynes} \qquad (6)$$

The force of a dynamo may thus be defined as a force of M C dynes at the rim of a pulley 10^7 centimeters in circumference. We may call M C the force factor of the dynamo.

Since M is the induced volts divided by the revolutions per second, it follows that $C\ M = \frac{C e}{n}$; but C e is the rate of doing mechanical work; i. e., the work done per second measured in watts, hence C M is the work done per revolution of the motor at any speed. If, then, we are given C and M, we can find the work per second, i. e., the rate of working, or the power, by simply multiplying the product C M by the revolutions per second.

Example 3. If the induction factor of a dynamo is five, and the maximum current one hundred amperes, C M = 500, and the rate of working at twenty-five revolutions per second is seen at once to be 12.5 kilowatts.

Many manufacturing firms have used the ratio of the watts to the revolutions per second as a basis of comparison of dynamos without perceiving its true significance, and have called this ratio the mass factor.

The fact seems to have been overlooked that the ratio of the induced volts to the revolutions per second is a constant, so long as the useful lines per pole remain unaltered, being, in fact, what we have termed the induction factor.

While the force factor and the so-called mass factor are one and the same thing, the latter is expressed in a way involving the idea of power and, consequently, of speed, while the former indicates the real nature of this ratio, showing that it is quite independent of speed, and, therefore, not a power unit at all, much less a mass unit, but a force unit.

Example 4. A four-pole railway generator, with the armature parallel connected (giving P = 1), has 440 conductors on the armature, with 16.1×10^6 lines per pole; the induction factor is seventy-seven, and the force factor for 600 amperes is $77 \times 600 = 46.2$ kilodynes; the output at 450 revolutions per minute is $46.2 \times 7.5 = 346$ kilowatts; the dynamo is a General Electric Company's M. P. 4, 300 multipolar railway generator.

Example 5. A ten-pole generator, armature parallel connected with 1,440 conductors and 28.6×10^6 lines per pole, will have an induction factor of 412.

The force factor for 1,500 amperes is $412 \times 1{,}500 = 618$ kilodynes, and the output at eighty revolutions per minute is 825 kilowatts. The dynamo is a Westinghouse ten-pole railway generator.

USE OF THE INDUCTION FACTOR IN DYNAMO CALCULATION.

SECTION III.

The induction factor forms a connecting link between the calculation for and the construction of a motor, and since it is the true basis of the dynamical action of the motor, it can be made the subject of calculation and enter into equations of any complexity.

Example 6. We have to design a motor that will draw a car at thirteen miles an hour, with a tractive effort of 680 pounds on thirty-three-inch wheels, with gear ratio 4.78 on a 500-volt line, the resistance of the motor being 1.3 ohms. If the mechanical efficiency is eighty-five per cent., the total tractive effort T must be 800 pounds.

If E be the tension of the line, d the wheel diameter, v the gear ratio, S the speed in miles per hour, R the resistance of the motor, the induction factor is given by the following equation:

$$M = \frac{E d}{11.2 v S}\left\{1 + \sqrt{\left(1 - \frac{8 R T S}{E^2}\right)}\right\} \qquad (7)$$

Inserting the given values in this equation, we find M to be 41.7. We also see from the equation

$$T d = 2.82 v M C \qquad (8)$$

that the current, when running with the given load, will be forty-seven amperes.

So that the motor must have an induction factor of 41.7 and carry safely 47 amperes; i. e., the force factor must be 1,960 dynes.

The induction factor may be made up in any way that is most convenient. If there are 720 conductors on the armature, and four poles, the armature, being series-connected, giving p = 2, we see from Equation 3 that we must have 2.89×10^6 lines per pole. Further, if the motor is series-wound, it must have the specified induction factor for forty-seven amperes in the field winding.

Equation 7 may be written in the form

$$M = 7.85 \frac{E d}{v s}\left\{1 + \sqrt{\left(1 - \frac{R T s}{11 E^2}\right)}\right\} \qquad (9)$$

where s is the velocity measured in feet per second, and d is the diameter of the rope drum of a crane or elevator.

Example 7. We have to design a motor for an elevator where the unbalanced weight to be raised is 2,000 pounds, the velocity 200 feet per minute, the tension of the line 125 volts, the gear ratio seventy-five, the friction equal to 1,400 pounds at the rim of the rope drum, which is thirty-six inches diameter, and the resistance of the motor 0.05 ohm; inserting these values in the equation, we find the induction factor to be 4.45, and the running current 130 amperes; the force factor is therefore 578 dynes. If p = 1, and A = 200, there must be 2.22×10^6 lines per pole. Since the pull at the rim of the rope drum is 3,400 pounds, when running at 200 feet per second, this motor would develop about twenty horse-power; and if the elevator had to act always at this speed, it would be sufficient to describe the motor as a twenty-horse-power motor; but this would give no information as to the ability of the motor to accelerate, since, at the moment of starting, the horse-power is nothing.

SECTION IV.

The current required for any given acceleration is given by the equation

$$a = 405 \times 10^{-4} \times \frac{v\ M}{d\ W} \times C_a \qquad (10)$$

where C_a is the current required (over and above the frictional or running current) to produce an acceleration of a feet per second in a mass of W tons[2].

Example 8. We have to start up the elevator car of Example 7 in two seconds; i. e., to get up a speed of 200 feet per minute in two seconds; a is then 1.67, and if we suppose the total mass to be moved to be five tons, the required current is twenty-two amperes, making a total current, at the start, of 152 amperes. The motor must therefore have a force factor of 676 dynes in order that it may start up in the given time.

If the distance from floor to floor were twelve feet, two seconds would thus be occupied in getting up speed, during which time the car would travel 3.3 feet, and the rest of the distance, 8.7 feet, would be covered in 2.6 seconds at 200 feet per minute, making a total time of 4.6 seconds for the whole distance. Nearly half the time is thus occupied in accelerating.

Suppose now that we had to reduce the time of starting by one-half; i. e., to start up in one second. One way of stating the case would be to say that we needed a "more powerful motor"; but so long as the frictional resistances and the final speed are to remain the same, the maximum horse-power of the motor remains constant, so that we do not need more power, but more force; i. e., we require a motor with a higher force factor.

We cannot alter M so long as the final speed is specified, so we must double the accelerating current, making the total current at the start 174 amperes. The motor would then be described as having an induction factor of 4.45, with an armature capable of carrying 174 amperes safely; i. e., the motor must have a force factor of 775 dynes.

Example 9. Take the case of the street railway motor of Example 6, with induction factor 41.7 and force factor 1,960 dynes.

The total available tractive effort was 800 pounds; allowing eighty-five per cent. mechanical efficiency left us with 680 pounds for useful effort. (The well known G. E. 800 street railway motor, made by the General Electric Company, has 800 pounds available for useful effort with forty amperes.)

If the track resistance for a car weighing ten tons be 200 pounds, this will leave us 580 pounds per motor, if there are two motors, for grades and starting, or we may say that of the maximum permissible current of forty-seven amperes, thirteen are used in overcoming gear and track friction, and thirty-four are available for grades or starting.

---

[2] Tons of 2,240 pounds and so throughout this paper. If tons of 2,000 pounds are found more convenient, the numerical constant can be changed.

Now, 580 pounds are equivalent to a grade of five per cent. for a ten-ton car, so that the motor would run a car of this weight at the given speed—thirteen miles an hour—up a grade of five per cent. Taking 680 pounds as the useful effort at this rate, the useful watts can be written (to within one-half per cent. of accuracy) as 2 S T or 17.7 kilowatts or 23.7 horsepower. This is the maximum rate of working.

These motors, however, will not be able to start the car on this grade. They can run the car when once started, but if it should happen to stop on the grade, they cannot get it started again, since the whole available current is used up in track friction and on the grade. We must draw more current from the line if we are to start up on the grade.

Equation 10 tells us that we can make the acceleration at the start anything we please, by increasing the current above that required for the grade and for friction. Let us find how much current would be required to start up in twenty seconds on a five per cent. grade.

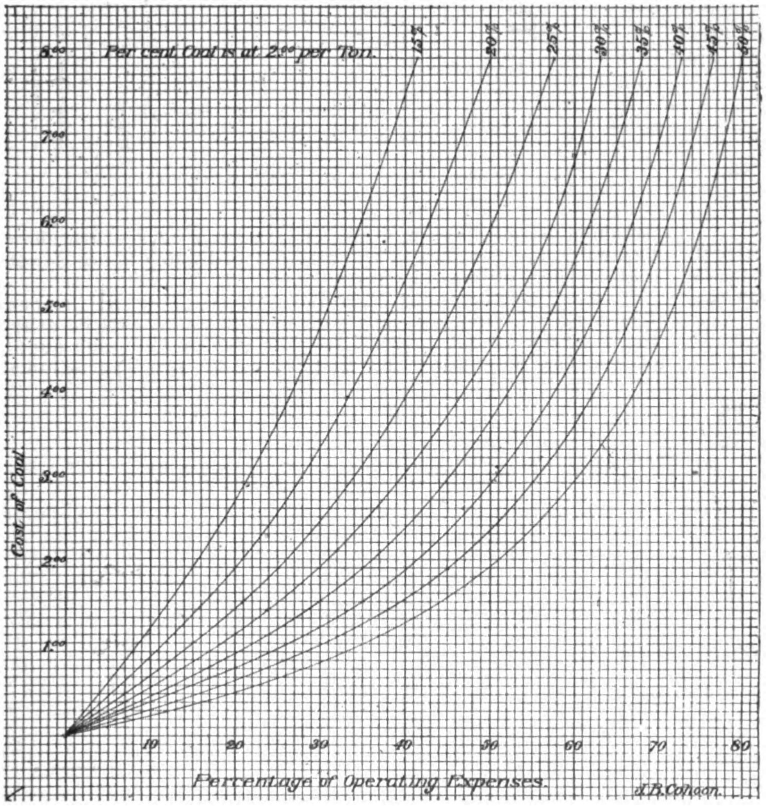
The final speed of thirteen miles an hour is equivalent to 19.1 feet per second; if we have to make up this speed in twenty seconds, the acceleration must be 1.91 feet per second, assuming uniform acceleration throughout. Inserting this value in Equation 10, remembering that each motor has to accelerate half the car, we find the required current to be twenty amperes, so that the total current from the line at the start would be sixty-seven amperes; namely, thirteen for friction, thirty-four for the grade and twenty for accelerating. The distance traveled in getting up speed would be about sixty-three yards.

The motors then would have to be capable of carrying sixty-seven amperes, and the force factor must be 2,790 dynes.

THE ESTABLISHMENT OF A BASE PRICE FOR CURRENT.[1]

BY J. B. CAHOON.

To bring incandescent lighting up to as profitable a basis as arc lighting is a serious problem, now that the people are accustomed to obtaining incandescent lights so cheaply, and certainly some stations are so situated that they cannot do it; others can by making a fight for it. Certain classes of stations are still giving flat rates in many instances, and the solution of the problem for them is to change over to meters and make the meter price one that will be equitable, both to the company and to the consumer. If it be decided that it is good policy to make a reduction to an equitable rate, then on what basis shall the company work? The thought has occurred to me, that it might be wise for the convention to adopt what may be called a standard rate, based on some factor or factors that will admit of application to every station in the country.



CURVE SHOWING RELATION OF COST OF COAL TO OPERATING EXPENSES.

A careful analysis of the prices paid per kilowatt hour for incandescent light in different sections of the country, seems to show that, in many instances, prices charged are based upon what somebody else has charged, rather than on what ought to be charged in view of the cost of the principal items entering into the operating expenses at each particular place. The two main factors that enter into operating expenses are wages and coal. If we separate wages into their natural subdivisions—administrative, distributive and productive—we find the amount expended directly for producing the current to be the dominating one in the matter of the cost of furnishing current to the consumer. Comparing the productive wages, we find that in different sections of the country there is very little variation in the amount paid to the engineer, to the fireman, to the coal-heaver and the auxiliary help in the machine room, so that, for practical purposes, it would not do to base the price of current on this factor alone. It is necessary, therefore, for us to look farther and seek some factor that shows a decided variation, and, at the same time, is one of the principal factors in the cost of producing current. The factor that seems to fulfill such conditions is coal. A glance over prices paid for coal in different sections of the country shows a very wide variation, and, at the same time, a consideration of the coal itself, as to its quality, shows a variation in evaporative power per pound of coal; which variations ought, strictly speaking, to enter as a factor in determining price, and, in order to get accurate results, should be so used: i. e., placing evaporative power of first quality coal at 12, then the price paid for coal should be multiplied by the ratio between 12 and the evaporative power of the coal used to determine the true value for comparison.

SUPERINTENDENT'S MONTHLY REPORT.

In determining a base price which should be charged per kilowatt hour, it is necessary to start with some kind of coal at a certain price, and which enters as a certain per cent. into the operating expenses. For this purpose, bituminous coal, with evaporative power of 12 and price $2 per ton delivered at the bunkers, has been taken, and it is assumed that with this coal at the price mentioned, it enters as a factor at practically 25 per cent. of the total cost of operating expenses of the company, said operating expenses including every expense attendant upon the production and distribution of the current and the administration of the company, also including taxes and insurance, but not expenditures for wiring of buildings or fixed charges. For example:

Blank Form of Engineer's Report.

Assuming cost of operating expenses at $40,000, cost of coal as $10,000 at $2 per ton, we obtain the cost of coal as 25 per cent. of the operating expenses. This gives one point of a curve which may be plotted for showing the effect of variations in the price of coal, other expenses remaining the same. Going further and plotting a curve on this basis, if the price of coal is $1 and other expenses remain the same, we then have the total cost of operating expenses as $35,000, of which coal is $5,000, or 14.28 per cent. If coal is $4 per ton, the operating expenses are increased $10,000, and total operating expenses become $50,000, of which coal costs $20,000, or 40 per cent. In a similar manner, using other per cents, other points may be determined and curves drawn through these points, the curves partaking of the form of a parabola passing through the origin; such curves are shown herewith; the division of the scale of ordinates being dollars, and of the abscissa per cent.

Remarks: ....

.... Superintendent.

If, now, we fix on 20 cents per kilowatt hour as the price which the consumer should pay on a basis of coal of evaporative power 12 and price $2 per ton, then if the same quality of coal can be obtained for $1 per ton, the price per kilowatt hour should be multiplied by one minus the per centum corresponding to the price of $1 per ton, or 20 × (1 — .1428) = 17.144; and if the price of coal be doubled, or $4 per ton, the price per kilowatt hour should be 20 × (1 + .40) = 28; the rule being to make the price, where fractions are obtained, the nearest whole number: thus, coal at $1 gives 17 cents per kilowatt hour. Similarly, the price that we should charge for arc lighting and power should be referred to the same standard. It should be clearly understood that the above assumption of coal at $2 per ton, and entering as 25 per cent. of the total operating expenses, is only made for the purpose of obtaining a starting point to present this idea to the members of the convention. In order to work on a satisfactory curve, and one that will fit the conditions of individual stations, each must figure out what per cent. of their operating expenses coal would be if they had to pay $2 per ton for standard coal, and start with this per centum as a basis on which to determine the proper curve for their own particular case.

Suppose each station were to make such a curve, and from it work out for itself the price which it should charge for current, and compare the price so obtained with the price that it is actually getting. This would then show whether the price should be advanced, in order to show a fair margin of profit. The purpose of bringing the subject up for discussion and for determining whether, in the opinion of the convention, it is advisable to establish such a basis, and, if it is wise to so establish a basis, whether it should recommend its adoption to the members.

BLANK FORM OF DYNAMO TENDER'S REPORT FOR LARGE STATION.

The question of blanks for showing output of the station and its cost is one that may well be discussed by the members of the convention, and an effort should be made to secure a standard set of blanks that will show these points in such a clear way that the information may be available for comparison and discussion in the conventions. I present herewith specimen blanks which show the system designed for our station, and among them will be noticed two forms of dynamo tender's report, marked A and B, respectively. The former we used prior to putting recording wattmeters on the alternating circuits, and the other, which we are now using, since the introduction of the wattmeters. The first blank entailed a considerable amount of work, and necessarily gave only an approximate result, but it was better than having no record at all, and, in one sense, the second blank, marked B, gives an approximate result also, as no recording wattmeters are used on the arc circuits. You will note on blank marked A that hourly readings of the alternating-current volt and ammeters are taken from ten o'clock p. m. of one day to three o'clock p. m. the next day, this being during the light-load hours, when the variations are small; during the heavy-load hours, from 3 p. m. to 10 p. m., half-hourly readings are taken. Many of the smaller stations would not feel warranted in going to the expense of purchasing recording wattmeters for their incandescent circuits, and for this class of stations this form of blank is recommended. For the larger stations, which can afford to keep more accurate records, Blank B is recommended. Blank C, the engineer's daily report, is probably the same in substance, if not exactly so in form, as is in use by a majority of the stations at the present time, and will be found, it is thought, sufficiently complete to give the results sought for without going into too many details.

Blank D is the superintendent's daily report, and is intended for the larger stations having a general manager, and is designed to give the latter a general idea of what has been done, what has been used, what material has been received, what is required and for which requisitions in due form will be made out. Blank E is the superintendent's monthly report made to the general manger of large companies, but should be made out by superintendents of small companies also and filed in a book kept for this purpose, so that they may at any time turn to it and get any information that is desired, or make comparisons between the output and cost from month to month. The main feature of this blank is that in a comparatively small space it gives the total cost of operation of the station for the month, the total amount of supplies used, the output of the station, the number of new lamps, motors, etc., connected, and also the loss, if any, in either lamps or motors. From the office the manager will have the report of the amount billed out for the current used for incandescent and arc lamps and motors during the month, and, by comparing the two, can readily ascertain whether the business for the month, as a whole, has been conducted on a profitable basis or at a loss; whether there has been an increase in the business; whether too much has been expended in one direction and not enough in another, and, in fact, can, in a brief space of time, analyze the entire business for the month in such a way as to give him the information that he needs, in order that he may intelligently conduct the business to a successful issue.

ADDRESS OF PRESIDENT NICHOLLS.[1]

IN arriving at a decision as to the most suitable place at which to hold the twentieth convention of the National Electric Light Association, the Executive Committee and your president were guided largely by the desire to select a spot where our members could have some practical illustration of the most recent advances in electrical development as applied to everyday commercial use on an extended scale.

Niagara Falls, N. Y., appeared to offer superlative inducements as our place of meeting, judged by this standard, and was accordingly given the preference; and with a knowledge of the programme that has been prepared for the instruction of our members and the many interesting features for the entertainment of themselves and their friends, I am confident that before the close of the convention, those present will unanimously be of the opinion that our choice was wisely made.

When we consider that only five years since many of us were in attendance at the fifteenth convention of the association held in Buffalo, and were listening to the discussion which followed Dr. Carl Hering's paper on "Transmission of Power," even the most sanguine of us but little imagined that in half a decade we should be holding our twentieth convention at Niagara Falls, principally with the object of seeing and realizing the actual application of motive power derived from the Falls, to some of the most novel and most important industries of the country.

To "harness Niagara" had long been a dream but is now an actuality, and who can foretell the resultant progress and advancement that we may be destined to celebrate within the next few years.

There is no parallel in history for such rapid development of any industry as that of the manufacture of electrical apparatus and its application, or, to be strictly correct and quote ex-President of the Association Mr. M. J. Francisco, who is an authority on the subject, the only parallel was when the world was created in six days out of nothing. Five years ago we were discussing the possibilities of transmitting power in small units to moderate distances; to-day the problem is solved and innumerable installations are transmitting power in large quantities for long distances, and yet we have only crossed the threshold.

---

[1] Presidential Address, N. E. L. A., Niagara Falls, June 8, 1897.

In this connection, I am of the opinion that the lecture to be given to-morrow evening by Mr. L. B. Stillwell will serve as a tidal mark. At the Buffalo convention we occupied ourselves in discussing the possibility or otherwise of transmitting Niagara power to Buffalo; Mr. Stillwell's paper will set forth the various actual applications of Niagara power at the present time, including transmission to Buffalo, and future presidents of this association will, in all probability, refer to his paper and draw comparisons when adverting to the strides which will be then have been made in the wider utilization of this mighty power, which for countless ages has been simply running to waste so far as any economic use is concerned and apart from its value as to the greatest scenic wonder of the world.

I fully appreciate the honor of presiding at this meeting, which, for the reasons I have just referred to, will be embodied in the annals of the association as marking an historic epoch in the advancement of the science of electricity as applied to industry, and it is, therefore, with more than ordinary satisfaction that I am authorized to state that at no previous period has this association been as prosperous, shown greater vitality or commanded such respect. It is now an acknowledged authority on matters electrical, its membership confers a privilege that has more than a sentimental value, and its gathering strength will offer a bar to use of powers municipal or corporate unjustly or arbitrarily directed for the purpose of destroying the capital investment of those who look to it for protection.

In union is strength, and to-day our membership numbers more active members than ever before, and the financial statement to be presented in due course by the chairman of the Finance Committee will show that after making provision for all expenditures necessary to maintain the usefulness of the association, an unusually large credit balance is at your disposal. It is certainly cause for congratulation that increasing prosperity has been followed by an access of dignity and influence and the more recent meetings have been remarkable for the greater interest that has been taken in the actual work of the association and the lesser attention that has been given to the merely social and entertainment features of the programme.

The desire to make the twentieth convention notably a business meeting has so far predominated that we have neither asked nor accepted any favors other than from the electric power companies, and several of the manufacturing establishments using electric power for the operation of their works.

Although several delightful and interesting excursions have been arranged for, the association has made, on behalf of its members a businesslike arrangement for the several trips and excursions set forth in the programme of the convention, preferring to pay our way rather than tax the courtesy of the transportation and other companies by accepting dead-head privileges.

In view of the fact that I have had occasion to communicate with our members from time to time during the past year by the issuance of printed "Interim Reports," referring to the work undertaken by your executive, it is unnecessary to give an account of my stewardship in this address, but I may say that many matters of urgent importance are pressing for settlement and which will doubtless receive the most careful attention at your hands during the next few days.

The list of papers to be read at this convention is an exceptionally good one, and the authors are of more than continental reputation, and I therefore trust that our members will show their appreciation of the care and study given to the preparation of these papers, by being present in force at every session, and taking an active part in the discussions that will ensue.

Notwithstanding the progress that has been made in the perfection of apparatus and the application of new principles, there never was a time when there was more to learn than now, and no more fitting occasion is likely to present itself to us to familiarize ourselves with the latest procedure in our chosen profession, and the papers to be read and the discussions thereon will find hundreds of thousands of readers and students, thanks to the electrical journals, of which we are all justly proud. No other art, science, industry or profession has been so well and faithfully served by an enlightened and progressive technical press as our own, and who can estimate the fair share of credit justly their due for the part they have taken in aiding and advancing the introduction of electromotive force in its many and varied applications.

As we have a lengthy programme before us and several important reports of committees to receive and discuss before we adjourn for midday recess, I now declare the twentieth convention of the National Electric Light Association opened and ready for the transaction of business.

REPORT OF THE N. E. L. A. COMMITTEE ON SAFE WIRING.[1]

CAPT. W. BROPHY, Chairman.

At the seventeenth convention of this association, held in New York City, a committee to be known as a Committee on Standard Electric Rules, consisting of five members, was appointed, with instructions to select one of its members or some other person to represent the National Electric Light Association in the National Conference on Standard Electric Rules.

This committee was the successor of the one that was appointed at the fourteenth convention of this association, known as the "Committee on Safe Wiring," and subsequently known as the "Committee on Standard Rules for Electrical Construction and Operation," which was discharged on its own recommendation at the same time. This last named committee has labored faithfully since its organization to bring about the much desired end, the establishment of a uniform standard set of electrical rules governing all electrical installations to be enforced by the fire insurance companies and municipal inspection bureaus. This task was no easy one for this committee. Its efforts met with fierce opposition from some and indifference on the part of others. It received some encouragement from the press at times, and no small amount of opposition at others. Some portions of the insurance interests looked upon it with favor, but a large portion opposed its aims and purposes. The principal obstacles to be overcome were:

First—Indifference on the part of those most deeply interested—those engaged in the electrical industries. They somehow believed that the fire underwriters of the country were more powerful than the municipal, State or even the United States Government; that any law, edict or rule issued by them, whether right or wrong, could be enforced and must be obeyed. For the benefit of this class, your committee must say, that such is not the case. The fire underwriters are receiving and disbursing agents of nearly the whole of the people of the country, receiving their money as a consideration for indemnity against total loss by fire. The larger proportion of the money they receive is returned as partial compensation for the losses sustained, the balance pays the expense of the business and a varying amount of profit to the holders of stock and the policy holders mutual insurance companies. The greater the care in selecting fire risks and the more careful the supervision of them while insured, the greater the profit.

The next obstacle to overcome was the prejudice of the average underwriter against electricity when introduced into the property he insured. To those who witnessed the methods adopted by those who installed the first electric light and know something of the losses sustained by the insurers and insured, this prejudice is excusable. Up to that time electricity had proved itself a useful and harmless servant, the only evidence of its ability to produce heat or flame was offered at the contact points of the telegraph relay and key, but when this very small spark was increased at the carbon points to such size and intensity as to rival in brilliancy the sun's rays, its power for good and evil was wonderfully increased. Those who could keep under perfect control the feeble battery current, did not possess the necessary appliances or knowledge to keep this new form of electrical energy under proper restraint, while the fire underwriters paid heavy tribute to it in the form of burnt offerings and in the shape of indemnity to the policy holders.

Under such circumstances who could blame these powerful bodies for taking alarm, and looking upon the new candidate for public approval with disfavor? They were between two fires as it were, those caused by electricity improperly harnessed, and that of enthusiastic admiration kindled in the breasts of their policy holders for the electric light; they would have it even if it did increase the fire hazard. How to get out of this dilemma was the burning question; they did not want to abandon a formerly profitable part of their business, but feared they must. Two remedies were tried: First, increased insurance rates was the penalty exacted for the introduction of electric lights. This plan proved ineffectual, because it did not prevent losses in excess of premium rates, and it opened up a new field for the illegitimate underwriter who preys on the insurer and insured alike in the end. The second remedy proved more effective. They called to their aid some of those who were supposed to know how to lead this new and unknown force along the straight and narrow path designed for it, and not permit it to wander into their domain and change fat dividends to heavy assessments. Such men were scarce, and most, if not all, of those engaged were obliged to learn by experience the best methods of procedure; the same can be said of those engaged in the electric business, the acquisition of such experience up to a few years ago proved very costly to the fire underwriters and others as well.

---

[1] Presented at the Niagara Falls Meeting, June 8, 1897.

Gradually fire insurance associations appointed one or more inspectors to examine the electric light wires, lamps and fixtures installed in their territory, and enforce certain rules and requirements generally made by themselves. With the rapid advance of the electrical industries changes in these were inevitable, but lack of uniformity proved to be a crying evil. The best and most reasonable requirements were formulated in the sections of the country where the electric light had found a foothold earliest. Most of the inspectors instead of profiting by the experience of those longest in the business and adopting the rules formulated by them, insisted on issuing productions of their own, so that the so-called insurance rules differed as widely as the excise laws of Maine and New York. Some sections of the country were fortunate enough to have men who were empowered to make rules and enforce them, whose elevation to such position did not make them dizzy and cause them to issue impractical requirements, the enforcement of which did not always serve any good purpose, but made life a burden to those who were so unfortunate as to come under their jurisdiction, whether manufacturers, contractors or producers of electrical energy. But other sections were not so fortunate. Among all the burdens that those in the electrical business have had to bear in the past, the whims and caprices of the authors of insurance rules were not the least.

The loss of time and money caused by conflicting requirements became so great in time, a movement was inaugurated by this association for securing uniformity or rules—a codification of the best and repeal of the productions of cranks and impracticals. This task was accomplished by your former committee, the results of their labors approved and the first national code issued by this association. It was also adopted by the insurance associations who thus recognized the good work performed. After the issue of this national code it was thought that all the troubles here described were ended. Such however was not the case, for while the best representative men of the fire insurance associations agreed that the electrical engineer or electric light superintendents were the proper ones to formulate the rules and requirements, and the insurance associations should enforce them, there were others holding subordinate positions who could not bear to have this sentiment put in practice. As a result of such feeling an organization known as "The Underwriters' National Electric Association," which has claimed the sole right to issue new or amend the original rules first issued by this association, and has in the past insisted that the electric and allied interest should have no voice therein. As time rolled by, and the organization increased in numbers this sentiment has changed somewhat due to the influence of broad-minded practical men who are members of it, and to the efforts of your former and present committees and last, but not least to those of the National Conference on Standard Electrical Rules, which was organized through the untiring efforts of the chairman of the Committee on Standard Rules for Electrical Construction and Operation, Mr. W. J. Hammer and his associates.

As a result of our combined efforts the last codification of and amendments to the national code is the result of the combined efforts of the National Conference on Standard Electric Rules and The Underwriters' National Electric Association. The right to do this is what your committee have contended for in the past and have finally obtained. Your present committee on standard electric rules selected its chairman to represent you in the National Conference on Standard Electrical Rules, which was organized at a meeting held in the city of New York on March 18 and 19, 1896, of representatives of insurance, electrical and kindred interests, consisting of the following organizations: National Electric Light Association, American Institute of Electrical Engineers, American Street Railway Association, National Board of Fire Underwriters, American Institute of Architects, International Association of Fire Engineers, Underwriters' National Electric Association, Factory Mutual Insurance Association, American Society of Mechanical Engineers, Western Union Telegraph Company, Postal Telegraph Company, American Bell Telephone Company, General Electric Company, Westinghouse Electric Company; The complete list of official delegates, complimentary delegates and organizations to whom invitations were extended, can be found in the report of the committee presented at the last convention and published in the last volume of this association's proceedings. That body appointed a committee on code, consisting of seven members, one of whom was your representative; to this committee was assigned the task of amending and codifying Standard Electrical Rules. At the time of the last meeting of the National Conference upon Standard Electrical Rules, a large amount of work was done by representatives of the various electrical, insurance, architectural and allied interests, tending toward the adoption of The One Single Standard Code of Rules. A pamphlet had been prepared embracing the various codes used most extensively in this country and abroad; and after these had been in substance considered, and many changes, omissions and additions suggested, it was deemed desirable that the results of the two days' careful discussion should be handed over to a special committee of seven, with the president a member ex-officio, which committee should draft a code based upon the lines suggested, and then refer the same back to the conference for its approval.

Since the meeting of the conference, the committee has by meetings and correspondence, carefully taken up the work assigned to it. The most important meetings were held October 16 and 17, 1896; and December 11 and 12, 1896. Between these two dates, i. e., December 8 and 9, the annual meeting of the Underwriters' National Electric Association was held, and at the October meeting of the Code Committee, it was decided that the committee through one of its members (Mr. Merrill) should submit the draft already prepared by them, to the Underwriters' National Electric Association to secure the benefit of their criticisms and suggestions, and with a view of insuring a hearty co-operation upon their part. It was arranged that a joint meeting should be held of our Committee of the Code, and a committee from their association to facilitate the preparation of the final draft of the code. This meeting, held in December, 1896, was very successful, and it was jointly agreed by the two committees that the title of the new set of rules was to be: (1) "The National Electrical Code;" (2) "That the National Board of the Fire Underwriters in printing the code, would give on the inside of the cover, due credit to the National Conference for its work, and place upon the cover, the names of all the associations forming the National Conference, as fast as these bodies give their indorsements of the code;" (3) "That as far as possible the code should be left in the form as then presented, save that the classification as recommended by Mr. French, be tentatively adopted, and after being set up by the printer, be resubmitted in "dummy" form for final consideration by the members of both committees. The members of the Code Committee of the National Conference having met in New York May 19, 1897, passed the following resolutions:

"Resolved, That each delegate who attended the National Conference on Standard Electrical Rules, be sent a copy of the Standard Electrical Code, stating that said code had met with the approval of the Code Committee of the National Conference, and the Code Committee of the Underwriters' National Electric Association, and stating the belief of our committee, that there was no necessity for calling the conference together as a body again, entailing as it would, a very considerable sacrifice of time and money, and requesting their immediate reply, if they acquiesce in this recommendation, and approve of the report submitted by the committee, and by the president, secretary and treasurer of the conference itself. In the event of their objecting and desiring that the conference as a body be called together as a body to receive the committee's report, answer is to be made within ten days, or their opinion is to be considered as favorable, and the code and reports published through the press by the Code Committee, and each delegate represented at the conference requested to bring same formally before his association for approval." A meeting of the committee was held in Boston on the 5th inst., at which its previous action was ratified and the code as a whole unanimously adopted. The National Electric Light Association was the first to adopt and issue a national standard code of rules, and if it now adopts the new codification of them it will not only be indorsing the unanimous findings of its committee, but the unanimous action of the Code Committee of the National Conference on Electrical Rules, which conference was organized under the auspices of the association; but furthermore it will be the first body represented in the National Conference to do so, and your committee earnestly recommends that it gives its approval.

MR. JOHN J. COOPER, the manager of Las Animas Light and Power Company, Trinidad, Col., says: "We think a great deal of The Engineer and would not be without it."

MR. J. L. GUILE, engineer and electrician of the Oxford, N. Y., Electric Light Company, writes: "I am very much pleased with The Electrical Engineer and get a great deal of information and many points from it. It also gives us an insight into what other people's experiences are with electricity."

THE NIAGARA POWER TRANSMISSION LINE.[1]

BY J. G. WHITE.

MY first personal knowledge as to the then proposed transmission line between Niagara Falls and Buffalo dates from the autumn of 1894 when the White-Crosby Company was asked to prepare and submit detailed plans, specifications and proposals for its construction. It was then found that the engineers of the Westinghouse and General Electric companies had both recommended the construction of circuits of three wires, adapted to the three-phase system, each wire having an area of about 330,000 circular mils. Beyond this no definite plans had then been determined on. The engineers of the Cataract Construction Company at that time considered it advisable to have the line built entirely of iron poles and accordingly detailed drawings and specifications were prepared and submitted showing alternative plans. The first included two entirely independent lines of iron poles, not less than 40 feet long, weighing something over two thousand pounds each. The second consisted of lines of poles of about the same height, weighing one thousand pounds each, set in pairs and tied together by deep trusses, which served both as braces against the terrific wind storms which sometimes sweep across Lake Erie and as a means of carrying part of the wires. A steel truss fulfilling admirably this double function was designed, which weighed about six hundred pounds, the company's right of way being 30 feet wide, and the lines of poles located 15 feet between centers. Several wooden trusses were designed for the same purpose, but, while better from an electrical standpoint, these were all so clumsy in comparison to the iron poles that preference was given to the steel truss. Various designs of poles were considered, including several built up from "rolled shapes," final preference being given to plain tubular poles on account of their ability to withstand equally strains from all directions, their appearance and the ease with which they can be kept painted.

Numerous designs for cross arms were also considered, including those made from "rolled shapes," composite arms (part wood and part steel), and those made entirely of cast iron or of wood. The latter two were preferred on account of the ease with which they could be designed to accommodate either wood or iron pins.

In determining the details for these alternative plans it was assumed that poles would be set in concrete and spaced one hundred feet apart; that each wire would weigh one pound per lineal foot; that the three wires composing each circuit were to be placed at the corners of an equilateral triangle having sides at least three feet long; and that the lateral strength of the line was to be not less than three times the forces produced by wind acting with a pressure at right angles with the direction of the lines, equal to thirty pounds per square foot on the projected surface of the poles, arms, insulators and wires, when the latter were covered with a coating of ice one-half inch thick.

As a matter of fact the heat generated by the current passing through the wires, together with the static effect tending to repel all particles of moisture coming in contact with the wires, this effect being quite noticeable on a ten thousand volt line, would combine to prevent the formation of any such coat of ice unless at a time when current was off the line. Any error thus introduced was on the safe side and consequently not objectionable.

Full proposals with detailed plans and specifications for the construction above outlined were submitted October 11, 1894, and the amended proposition for carrying out the construction on the same general lines was submitted March 13, 1895. Nothing further developed in the matter until June, 1896, when new proposals were asked for the construction of the line on the assumption that white cedar instead of iron poles would be used throughout. Such proposal was submitted June 18 and accepted some days later. In working out the details of the line as built, the same general assumed data above given was used.

When the route for the line was finally determined on its length was found to exceed 27 miles instead of being 25 miles, as previously assumed, and consequently the area of the wire was increased from 330,000 to 350,000 circular mils. The wire actually erected is composed of 19 strands, having a combined area of full 350,000 circular mils, and weighs nearly 6,000 pounds per mile.

In designing a transmission line, the three most important factors probably are: 1. Its ability to carry its full load continuously and without interruption. 2. Cost. 3. Efficiency.

The first cost of power used to develop current for a transmission line is usually low, wherefore the efficiency of the line is not of primary, although of great, importance. Those of us familiar with the development of the street railway motors have seen in practice an illustration of the fact that efficiency is not always a controlling factor. There has probably never been in general use another street railway motor so efficient as the Sprague No. 6. With units of an ordinary size a short circuit on a line carrying ten thousand volts, even if through a defective insulator, a wooden cross arm and a wooden pole would make itself manifest at the power station by the opening of a circuit breaker, the blowing of a fuse, or some simliar method. With the huge generators which furnish power for the line the effects are different. During one night last fall, while an attempt was being made to operate the line on temporary insulators, the best obtainable at the time, the ends of no less than five of the large cross arms used on this line were burned entirely off; and this too without any manifestation having been made at the station that anything unusual had occurred. This naturally raises the questions whether it is possible to procure insulators which can be depended on to maintain the insulation on a circuit carrying 10,000 volts or over, and whether it is not good practice to have fewer poles, and consequently less weak spots in the form of insulators.

There are two sides to this question, and both deserve serious consideration in designing any transmission line. Let us assume that poles are set 100 feet apart and allow a sag in wires between supports of twenty inches, or one-sixtieth of the length of the span. We find that the area of the wire in use on this line is .267 of one square inch, and that its tensile strength, even assuming a high value for soft copper is about 10,000 pounds. Allowing the same deflection, one-sixtieth of the length of the span, this determines the maximum safe distance between poles as 178 feet, allowing a factor of safety of four, and shows that the cables might be expected to break if the span were lengthened to 712 feet, not allowing for wind pressure or extra load due to ice.

Assuming a tensile strength of 8,000 pounds per square inch for yellow pine, we find that the larger cross arms used on the line, which are twelve feet long and nearly five inches wide by six inches high, would support a load of 270 pounds on each end without bracing, and of 360 pounds on each end with the steel angle braces used, and this too with a factor of safety of ten, an unnecessary margin when we consider that the arms are all specially selected heart, long leaf Georgia pine. Similarly these cross arms would have the same factor of safety carrying three power cables on each side with spans 177 feet long if without braces, and 266 feet long with braces. Besides giving this added strength, the braces used on this line prevent such vibration and oscillation as usually takes place with the ordinary strap iron braces, such oscillation being the cause of many of the petty troubles on ordinary lines. These braces were each made from a single piece of steel angle 2 x 2 x ¼ inches bent to shape and forming when finished a truss 18 inches deep and five feet in extreme length, their weight being a little over 20 pounds each. Assuming again that poles are set 100 feet apart, we find that 12 wires with cross arms, insulators, etc., would present an area to the wind aggregating about 67 square feet, and that consequently each pole would be subjected to a side strain when wind pressure was 30 pounds per square foot, of about 2010 pounds. A sound 50-foot cedar pole, 8 inches diameter at top and 18 inches diameter at butt, 8 feet being held rigidly in the ground, would be capable of withstanding before breaking a side pressure near its top of only about 4,900 pounds and of only about 3,400 pounds when a layer 2 inches thick had decayed around its circumference.

With spans of 100 feet the pole would, therefore, have a factor of safety of only about 2½ when new, while the wires would have a factor of safety of about 7, and the cross arms of about 26. The advantages of having cross arms amply strong are so evident, and the possible reduction in cost such an insignificant part of any ordinary line carrying much copper, that it would seem foolish to reduce the strength size of these in order to bring their strength down to correspond with other parts of the line.

It is evident from the above that the weakest point of this line mechanically is the pole, in spite of the fact that as advised by one of the prominent members of your Executive Committee final decision was made in favor of spacing the poles 75 feet apart on straight, and proportionately closer on curved parts of the route. The only reasonably safe and practicable method of decreasing the number of weak spots furnished by the insulators would be to use poles larger than eight-inch tops, or to brace the poles to withstand this wind strain. Fifty-foot poles having tops greater than eight inches are now hard to find, and although 35-foot poles were used on a part of the company's private right of way, nevertheless many 50-foot and even a few 65-foot poles were required to avoid obstructions and for crossing railroads and highways. The only feasible plan, therefore, would seem to be to brace the poles laterally, which can readily be done if set in pairs, but which would be very difficult to accomplish in a satisfactory manner with a single line.

---

[1] Read before the N. E. L. A. Abstract.

This naturally brings us back to the question, Are insulators such insurmountably weak links in such a chain, and is it not possible to get insulators which can be depended on even when supporting wires under a pressure of 10,000 volts? This can be most satisfactorily answered by again narrating the experience with this line. During the past eight months insulators have been sent to Niagara Falls by four of the works which are among the first six in this country in the production of porcelain for electrical use. Of a sample lot of ten received a few days ago for test from one of these factories, one had broken in transit, eight broke under the strain of electrical pressure varying from 16,000 to 36,000 volts, and the last broke under 40,000 volts strain. This latter would seem to be a minimum safe test limit for any insulator expected to sustain a regular strain of 10,000 volts and is a test which any mechanically good, well vitrified insulator of ordinary design will pass. As several previous lots from the same factory showed even poorer results, the manager of that company states that he hopes within a few weeks to be able to furnish insulators which will stand a 40,000 volt test. It is only fair to state that these insulators were of a smaller type than, and different design from those in use in the Niagara line. Several lots of somewhat similar insulators from another factory gave about the same results.

Several thousand insulators of a diameter almost equal to the round type now on the line, but of a design somewhat different in details, were furnished by a third porcelain works. These were all supposed to have been tested and to have successfully withstood a pressure of 40,000 volts at the factory before shipment. When, however, these were tested at Niagara Falls by Mr. Lincoln, the electrical superintendent of the Cataract Construction Company, it was found that a large majority of them broke down under a 40,000 volt test, illustrating that a dry test, such as had previously been made, is useless for practical purposes.

The method of test used at Niagara Falls was as follows: The insulators were set inverted in a shallow iron pan in lots of about 20, the bottom of the pan being covered with an inch or two of water containing a little salt. A little of the same brine was poured into the pin hole of each insulator, and into this was thrust a small piece of metal such as an ordinary iron spike or the small round zinc rod from an ordinary sal ammoniac battery, this being connected to one side of the testing circuit, the other being connected to the pan containing the insulators. After the metal rod had been placed in the brine in the pin hole of an insulator, the primary circuit of the testing transformers, specially built for the purpose, was closed; and if the insulator was weak, this was quickly manifested by a series of sparks through the punctured porcelain. Experiments made with pure water and with brine showed that there was no difference in the results; but that any weakness was manifested a little more quickly with brine, besides which the salt imparted the characteristic bright sodium color to sparks otherwise almost colorless and difficult to detect.

As it was important that the line should be ready to deliver current by a specified date, the test was reduced on these insulators to 20,000 volts, and all which withstood this pressure were passed for temporary use. These insulators were later replaced by some of those now on the line, all of which successfully passed a 40,000 volt test made as above described. A lot of the temporary insulators illustrated the old saying that every rule has its exception, for when after removal from the line they were tested under 40,000 volt pressure, a solitary insulator from a total of 1,150 was able to pass muster.

Of the insulators shipped by the fourth factory, and of the two types now on the line, about 25 to 40 per cent. were usually found to be defective, breaking down under 40,000 volts, this percentage decreasing in the last shipments received. It is, however, worthy of special note that since the last of the temporary insulators were moved from the line, there has not been one minute's suspension of current supply due to defective insulators. During this time, some three or four months, three insulators have been replaced, none of these being of the oval type. Two of these three had been broken while being put in place, and the third was broken by a stone or other missile. In all three cases only the outer petticoat was broken, and the insulator continued to do satisfactory service until such time as it could be replaced without affecting the operation of the line.

Apparently, therefore, it has been demonstrated that it is possible to secure insulators which are reliable. That there have been no greater troubles in the past from defective insulators is probably due to the fact that most of the large transmission plants in operation under high voltage up to within a few months have been in the far West, where the climate prevails very different from that natural to this immediate region.

In the above and other experiments with insulators some interesting facts have been developed and are worthy of note. The insulating strength of porcelain depends almost entirely on the thoroughness of its vitrification and very little on its thickness, a thin china tea cup having successfully withstood a pressure of 60,000 volts, while a coarse piece of porcelain two inches thick was readily pierced by 20,000 volts. It is therefore, practically unnecessary to test electrically any insulator which, when broken, will not pass a good absorption test, using red ink or other fluid.

It is quite, if not entirely, impossible to puncture a glass insulator, even an ordinary pony telegraph insulator, notwithstanding any pressure which can be applied, the last being determined by the pressure which will send an arc around the insulator. The objection to using glass insulators in the past has been due to the difficulty in getting a well annealed and mechanically strong insulator, of such massive design as is needed for this work and to the hygroscopic property of glass, which is not shared by porcelain. The first can unquestionably be overcome by care in manufacture. The importance of the second has probably been exaggerated in most calculations made in the past, due to an inadequate appreciation of the static effects of 10,000 volts in warding off snow flakes and drops of rain, and to a less extent of the rapidity with which water falling on such insulators is evaporated by the heat of the current leaking over the surface.

It is consequently reasonable to expect that the use of glass insulators for high voltage lines will greatly increase with improved manufacture. Meantime any lines erected should have the best obtainable porcelain, and every insulator should be subjected to test.

Before closing it is natural to ask, "Is the line as built a genuine success? Can it be depended on, and is it effective?" In answering let me give briefly some of the facts. The line now in operation is over 25 miles long, of which the last 4,000 feet is underground, the current being carried in lead covered cables with rubber insulation, these having been drawn into terra cotta duct conduit built specially as part of this line. These cables successfully withstood a test of 40,000 volts, are guaranteed for five years under working pressure up to 25,000 volts, and were punctured during test only by a pressure, estimated by Mr. Lincoln at about 80,000 volts. They have given no trouble since current was first turned on the line, November 15 last, except at two joints imperfectly made. Except for the short time needed to repair one of these joints there has not been a single shut-down chargeable to the transmission line itself, since the last temporary insulators were removed some three or four months ago.

A number of interruptions to service have occurred during that time, due to derricks used on the work now being done on the Erie Canal hitting wires, undermining of poles and conduit by this work and to allow new lightning arresters to be put in circuit at transformer houses. Except for these extraneous and unusual causes the service has been perfect with the one slight exception above noted. One short interruption early last winter was due to the dead limb of a tree blowing across the wires, illustrating the fact that all trees should be cut down for some considerable distance on both sides of any high voltage line. The line shows an insulation resistance of some 250,000 to 300,000 ohms on wet, and about 1,000,000 ohms on dry days, this being between any one of the three wires and the ground, the insulation therefore varying from six to twenty-five million ohms per mile of wire.

The actual working efficiency as shown by the wattmeters in the low tension alternating circuits at Niagara and the direct current 500-volt circuit at Buffalo was 79.6 per cent., this being for a considerable period and a fluctuating load. This efficiency included loss in step-up transformers, line, step-down and rotary transformers. It is probable that any decrease in this due to greater line loss with larger load would to a considerable extent at least be offset by increased efficiency of transformers. In view of these figures we hope you will feel warranted in endorsing the opinion that Niagara power is now being satisfactorily delivered in Buffalo.

One of the questions often asked is why this entire line was not placed underground. One of the principal reasons was that the line of twelve wires, having a capacity of 20,000 horse-power would cost, irrespective of right of way, fully a million and a quarter of dollars if underground, and only about one-third of that amount overhead, making a serious difference in interest charge. Of such total costs about 20 per cent. would cover cost of conduit complete, including manholes, the remaining 80 per cent. being lead-covered cables. Of the overhead construction cost, slightly over 80 per cent. is bare copper wire, less than 10 per cent. covers poles set in place, and about 3 per cent. covers insulators.

It is probable, therefore, that the depreciation of the lead-covered cables will greatly exceed that on pole line, the first cost being some thirty times as great, and the depreciation of the bare copper being negligible. Aside from this experience to date has not demonstrated that the underground line would be more reliable, which alone could justify the increased depreciation and interest charge.

As a final deduction it seems reasonably certain that it is now possible to build either overhead or underground transmission lines, even in regions subject to much cold, damp weather, capable of carrying current at 10,000 volts or higher pressure, which can be operated with efficiency and every assurance of uninterrupted service.

REPORT OF COMMITTEE ON STANDARD CANDLE-POWER OF INCANDESCENT LAMPS.[1]

DR. LOUIS BELL, Chairman.

THE task that your committee undertook was to draw up a suitable specification for a standard incandescent lamp and to devise a proper method for the commercial application of this standard. This problem divides itself into the three following heads:

I. The determination of a standard of light and the method of applying it under commercial conditions.

II. The specification of a direct, simple and rapid method by which the members of this association and other users of incandescent lamps can apply such a standard of light to the testing of commercial incandescent lamps.

III. The specification of a normal standard of luminosity, to which commercial incandescent lamps shall adhere.

I. The first task was the selection of a primary standard of light to serve as the basis of operations, proper apparatus and methods for its utilization for the purpose in hand. There are in use as primary standards of light a considerable variety of sources of light, to wit: Two standard candles, English and German; three standard lamps burning definite substances under definite conditions, the Carcel lamp, the Harcourt Pentane lamp and the Hefner-Alteneck amyl acetate lamp; one standard gas light, the Methven, and, finally, the Violle platinum standard, one square centimetre of platinum at its point of solidification. In addition, there are more or less desirable forms of photometer.

Even assuming a standard light and method, the comparison of an incandescent lamp with it may be under all sorts of conditions and at all sorts of angles.

In this state of affairs your committee requested the co-operation of the American Institute of Electrical Engineers, and, through the courtesy of the council, the problem was referred to the Committee on Units and Standards. The following determinations were presented by that body, in which your committee, having discussed the matter in joint conference, concurs:

A. The Hefner-Alteneck amyl acetate lamp is recommended as the primary standard, it being, on the whole, the most reliable and uniform. It possesses the additional advantages of having been subjected to most exhaustive tests to determine its behavior under different conditions, and of being readily obtainable in standard form from an authoritative source.

B. The Lummer-Brodhun photometer screen is recommended as being well suited, from its great sensitiveness, to exact and refined determinations.

C. It is recommended that in testing incandescent lamps by these means the lamps be revolved on a central axis at the rate of about two revolutions per second. This process gives the mean luminosity in the plane of revolution without a multiplicity of measurements.

D. It is recommended that, in so far as the conditions of commercial testing allow, the normal standard incandescent lamp be rated in terms of its mean spherical candle-power.

It now became the task of your committee to put these recommendations in such concrete form as would most directly render them useful to the members of this association and others interested in the everyday work of testing lamps.

For easy and accurate photometric work it is highly desirable that the lights compared should be of nearly equal color and intensity. The Hefner-Alteneck standard is of about one candle-power, and has a slight orange cast, so that while giving very precise results in careful hands, it is somewhat inconvenient for rapid comparisons. Your committee, therefore, recommend the use of the Hefner-Alteneck standard to prepare secondary standards for commercial use. These standards should be incandescent lamps of uniform shape, construction and character, standardized with the greatest attainable exactness and suitable for direct comparison with commercial lamps. In testing lamps by these secondary standards, the above-mentioned photometer screen being rather difficult of manipulation for rapid work, we recommend a form of photometer designed specifically for use in connection with a standard method of measurement hereinafter described.

To avoid the complication incident to spinning both the secondary standard and the lamp being tested, we advise placing on the socket of the secondary standard a definite mark showing the direction in which the directly given light is exactly equal to the mean determined by spinning. By placing this mark toward the photometer screen and in the plane of the photometer bar, only the lamp under test need be spun.

It is obvious to your committee that the common rating of incandescent lamps by their mean horizontal candle-power is objectionable and should not be continued. In the first place, as incandescent lamps and other lights are practically placed, one is invariably below them, and hence, if their axes are vertical, below the principal plane of illumination. If their axes are tilted we still get the full advantage of but a portion of this principal plane. Second, it is unfortunately only too easy to produce lamps in which the maximum light is only in the horizontal plane, but which in all other directions give decidedly poor illumination. Such lamps are practically of far less than their rated candle-power.

The ideal distribution of light would be a uniform spherical one, except in so far as the socket might prevent. In any ordinary position such a lamp would distribute at least half its light uniformly downward, where it would be of most use. In practice this cannot be readily obtained, but it is easy to produce a lamp that will give a fairly uniform distribution, at least below the plane of the socket when the socket is uppermost. Rating lamps by mean spherical candle-power will strongly tend to produce lamps having such a distribution. The measurement of mean spherical candle-power is, however, a very troublesome matter, and, even under the most favorable circumstances, is a slow process, not readily applied to commercial testing.

Your committee, therefore, cast about for a practical method of testing, such as would insure a good and useful distribution of light and would be easy to apply. In other words, how shall the light of a lamp be measured so as to rate it as nearly as practicable on its useful distribution of light?

After looking into the distribution of light actually given by commercial lamps, your committee believe that the light given half way between the vertical and horizontal planes forms the best simple criterion available. This can readily be measured by rotating the lamp socket down, with its axis inclined 45 degrees toward the photometer screen and in the plane of the photometer bar. This measurement gives a fair mean between the horizontal and vertical illumination, and in most commercial lamps is a tolerable approximation to the mean spherical candle-power. Furthermore, it insures a good downward distribution of light, even in a lamp designed to meet this particular method of measurement.

Your committee are fully aware that no simple measurement can truly calculate the effective luminosity of all forms of lamp, but recognizing that in the rapid commercial testing of lamps a single simple measurement is highly important, strongly recommend this one as most nearly meeting the necessary conditions.

By this process of simplification we have reduced the measurement to be made by the use of incandescent lamps to the comparison of two nearly equal and similar lamps, of which only the lamp under test has to be revolved. Furthermore, in much commercial testing it is not necessary accurately to determine the candle-power of the lamp under test. In most cases it is sufficient to determine that it falls within certain definite limits prescribed for the normal standard lamp. Hence, it will generally not be necessary to make an exact setting of the photometer screen, but merely to observe the conditions existing when the screen is resting against stops in two fixed positions, one corresponding to the minimum permissible candle-power of the lamp under test, the other to the maximum.

The actual process of testing would then be as follows:

Having placed the standard lamp in its marked position, and adjusted the voltage to its normal value, the observer would then place the lamp to be tested in its socket and spin it, having first pushed the photometer screen against the stop. If the candle-power was all right on this test, he would pull the screen against the other stop and look again. The whole process need not take over fifteen to thirty seconds, according to the skill of the operator, and would show definitely whether or not the lamp fell within the standard limits. Your committee will in due season place in the hands of the secretary a full specification for the making and use of a simple photometer, designed to be used in the manner just indicated.

---

[1] Presented at the N. E. L. A. Convention, Niagara.

We now reach the third portion of our task, to wit: the definition of a normal standard to which commercial incandescent lamps should conform. At present there is much confusion on this matter, and we feel that it must be reduced to terms at least simple and definite.

It seems to your committee inadvisable at present to complicate the situation by introducing considerations of efficiency, life and variations of candle power with life. Efficiency, the candle-power being known, is settled at once by the application of a volt and ammeter, and the matter of life may properly be left to the natural course of competition to settle. Variation of luminosity with time is a matter of importance, and, after a general and uniform standard has been promulgated, may properly be considered. For the present, however, your committee is of the opinion that attention should be confined to the adoption of a standard specification for light alone, and the production of suitable apparatus for testing the fulfillment of this specification. To this end we believe it best to rate commercial incandescent lamps by the illumination obtained when the lamp is spun with its tip inclined 45 degrees from the vertical, toward the line of observation, and to specify the rating in candle-power, this being the most familiar measure of light and definitely legalized in some States. The ratio between the English standard candle and the Hefner-Alteneck lamp has been accurately determined by several experimenters, so that it is easy to pass from the latter to the former, thus avoiding the extreme unsteadiness when used directly.

As a matter of manufacture it is very difficult to produce a lamp of a given voltage for an exact specified candle-power. Hence certain limits must be set, rather than a certain definite candle-power, and these limits should be so drawn as to meet both the conditions of manufacture and to insure a reasonably close accordance with the rated intensity. For an incandescent lamp rated at sixteen candle-power (oblique zonal as above indicated), fifteen candle-power for the minimum and seventeen candle-power for the maximum afford limits fair to all parties concerned, and these your committee recommends.

As to the method of procuring and distributing the secondary standards to be used with the photometric method already outlined, the following is desirable. Incandescent lamps of uniform shapes and in standard sockets, with filaments uniform in shape and section, in all respects unmarked, should be furnished by the lamp manufacturers to the standardizing committee. These lamps should then be properly aged and standardized at such voltage as may give precisely sixteen candle-power with the greatest attainable precision, marked on the sockets with a reference line, numbered, certified and dated. They should then be turned over to the secretary for distribution at a price covering the cost of standardizing and handling.

Your committee therefore recommends:

1. That the standard sixteen candle-power incandescent lamp shall be a lamp which, when measured in rotation at about the rate of 180 revolutions per minute, with its axis inclined 45 degrees, as herein specified, shall give not less than fourteen one-half and not more than seventeen one-half candle-power, and that every ten lamps shall average between fifteen and seventeen candle-power.
2. That your committee shall be empowered to make suitable provision, with the consent of the Executive Committee, for the production of the secondary standards and to request the co-operation of the American Institute of Electrical Engineers in the formation of a non-partisan committee to supervise and certify said lamps.
3. That the secretary be directed to undertake, under the direction of your committee, the procuring of lamps for standardization, their distribution when standardized, and the preparation and distribution of the specifications of your committee for a standard form of photometer and a standard method of employing it.

MR. A. C. STEVENS, manager of the Oelwein, Ia., Electric Light and Power Company, writes: "We are very much pleased with The Electrical Engineer. Each number is full of interesting and valuable information."

VERESTCHAGIN, the Russian artist, says that the piercing brilliance and startling liveliness of Emperor William's eye are truly remarkable. "I have seen such eyes but once before and they were Edison's." If this is true, we are sorry for Edison. Our own experience with the "Old Man's" eye has been quite different, and we must admit that even in his most jocular moments he never tried to trip us up with his sword.

LETTERS TO THE EDITOR

THE LEGAL STATUS OF THE JANDUS ELECTRIC CO.

We have been informed that a notice has been generally distributed by the Jandus Electric Company to the effect that their contract with this company as exclusive selling agents has been terminated, and that they will not hereafter supply their lamps through this company.

I beg to inform you that the action of the Jandus Electric Company is unwarranted and illegal. We have taken immediate steps in the courts to compel the Jandus Electric Company to recede from its position and to continue to supply us with lamps as heretofore under the contract which we have with that company, which has continued for two years without interruption and which has still five years to run at our option.

It is not necessary for us to comment upon the action of the Jandus Company in the premises, except to inform you that our rights will be protected to the fullest extent of the law, and the interests of our customers will receive equal care and protection.

We are advised by our counsel in this city, that the Jandus Company will be compelled to comply with the precise terms of its agreement with us, and that an adjudication to that effect will be procured within a very few days.

MANHATTAN GENERAL CONSTRUCTION CO.,
S. MARSH YOUNG,
Vice-President and General Manager.
New York, June 8, 1897.

LITERATURE

THE LOCALIZATION OF FAULTS IN ELECTRIC LIGHT MAINS.—By F. Charles Raphael. New York: D. Van Nostrand, 1897. pp. 180, 5½x8½ in. Illustrated. Cloth. Price, $2.

Fault finding is generally credited with being among the easy things to do, but many an electrician would be willing to go on record on the contrary proposition.

In the present work, which is reprinted from the columns of the London "Electrician," the author describes a considerable number of methods for localizing faults in both high and low tension mains, with special reference to tests while the current is on.

Electrical engineers operating underground systems will be interested in the description of Dr. Kallman's excellent system of fault-signaling networks, in which the pressure wires are employed for localizing faults, a method which ought to be better understood than it appears to be, and which has worked very successfully in Berlin.

The descriptions of testing instruments specially adapted for this class of work will also prove helpful to many. The book is well supplied with formulæ, that bugbear of the "practical" man, but when it comes to testing out four and five-wire systems they are simply indispensable, and besides even in simple work they must be used to some extent, if rule of thumb methods are to be avoided. The book will prove of value in the hands of all central station electricians.

TAUNTON, MASS.—The city is to buy the plant of the Taunton Electric Light Company for $125,000.

HOLYOKE, MASS.—A bill is going through the Legislature which enables the Holyoke Street Railway to carry freight and small parcels.

COUNCIL BLUFFS, Ia.—The nuptial knot was tied recently on a trolley car plying between Council Bluffs and Omaha, and the conductors are quite nervous now about being suddenly roped in as witnesses to a runaway wedding.

AT CLEVELAND, O., and other points adjacent, the Lake Shore Railroad has placed commutation tickets on sale with the object of preserving its suburban travel against the serious inroads of the trolley competition. This is regarded as the beginning of a cut-rate war all around.

VOL. XXIII. NEW YORK, JUNE 16, 1897. No. 476.

THE NIAGARA N. E. L. A. CONVENTION.

IN every respect the convention of the National Electric Light Association, at Niagara Falls last week, must be regarded as a great and brilliant success, far beyond that which was expected by those who had worked hardest to secure a happy result. The attendance was large; the papers were excellent and timely; the devotion to work was exemplary; harmony prevailed; the weather rang the changes so that the Falls could be seen in every aspect, and a good choice was made of officers to carry out the programme of usefulness to which the association has for some years past so consistently pledged itself. President Nicholls retired from office in a literal blaze of glory.

One of the most notable achievements in recent electrical history is the adoption of the National Code. That a large number of important national bodies could be induced to cooperate in a vital matter where jealousy was inevitable, that rules could be formulated and agreed to by all, and that the work could be carried through to a definite issue, seemed wellnigh impossible. Many people said the case was hopeless. But necessity has prevailed, and the National Code of Wiring now stands a solid, tangible reality. Capt. Brophy, Mr. W. J. Hammer, Prof. Crocker, Mr. J. I. Ayer and the other loyal workers deserve the thanks of the whole electrical art in America for their labors, and are to be congratulated on their hard won success; but the association above all is to be felicitated. It was an association campaign, and had the body never done anything else this piece of invaluable work would be sufficient to justify its existence. It was a pleasant thing that the association could by mere chance be the first to stamp with unanimous assent the work which it had itself begun.

One of the most significant things was the election of Mr. Insull as president for 1897. The last meeting of the association at Niagara was conspicuous for discord and angry feeling. This recent meeting showed that in some respects at least a better understanding has been reached, for Mr. Insull happens to be also the president of the Edison Association. That the N. E. L. A. and the Edison body should choose the same man as their president would have been deemed absurd a few years ago, but time has wrought many changes, and the event signalises the beginning of a new period in the development of electric light and power. Mr. Insull is a strong man, full of individuality, anxious to be useful, experienced in affairs far beyond the ordinary, and although young has spent his life in the upbuilding of the electrical arts. Like his predecessor, he knows all there is in manufacturing, but as a central station manager on the largest scale he is in a position of peculiar advantage to harmonise conflicting conditions while promoting the welfare of the great local lighting industry. We are satisfied from what we know of Mr. Insull that the double election must gratify him deeply and yet be regarded as an opportunity for work as useful and helpful as any he has done in his exemplary career as an adopted son of America. It is certain that Englishmen cannot complain of lack of recognition of their merits in this country.

Coming to the papers we may say that Mr. J. G. White's, describing the operation of the Niagara-Buffalo line, was full of just such information as is wanted at this stage of the proceedings, when long distance transmissions are contemplated on all sides. From what Mr. White stated and what was brought out in the discussion, it may be taken as a fact that this transmission line is an established success, the small difficulties experienced in the first few weeks of its operation having been entirely overcome. Naturally the integrity of these lines depends primarily upon the quality of the insulators employed, and it is gratifying to know that American manufacturers have so easily and rapidly succeeded in supplying an article adapted to the purpose. The experience with the early insulators show that what is wanted in a high tension insulator is not so much quantity as quality; that is to say, a small insulator thoroughly vitrified is far more effective than a large one incompletely vitrified. Another interesting and unexpected point, is the benefit derived from the electrostatic action of the lines, which repel water and snow flakes, while the heat evolved by the leakage over the insulators keeps them clear of ice and snow. Mr. White was of the opinion that the use of glass as an insulator would increase in time on high tension circuits, it being merely a question of making this material of the proper strength and toughness to stand the mechanical strain which is put upon it, its electrical properties being well adapted for the purpose. We need only cite as an instance of this the 6,000-volt alternating line at Springfield, Mass., described in our last issue. It has been a perfect success in all weathers. As to the adoption of wooden poles in preference to iron the projectors of the line probably feared to risk a metal structure, although iron poles have been used on the transmission between Tivoli and Rome. The climatic conditions, of course, in the latter installation are not nearly as severe as those encountered at Niagara, and hence probably the adoption of the wooden poles at the latter place. But we note that for the Lachine transmission iron poles will be used, and the results obtained with them will probably be a determining factor in future pole line construction for long distance power transmission. Incidental to Mr. White's paper the discussion touched upon the effect of long distance transmission rivalry on the commercial prospects of local plants. The opinion prevailed among several of the members of the association that there was nothing to fear from competing long distance transmissions owing to their limitations of cost. But even where they are profitable it is more than probable that long distance transmission will be a direct benefit and gain, not only to its promotors, but to the owners of existing plants in the cities to which such power is transmitted. In support of this view we need only mention the fact that, in nearly every instance in which power has been transmitted for long distances into cities where private local plants previously existed, the local plant has leased power from the power transmitting company,—where the two were distinct organizations,—and was, therefore, a direct gainer by the bringing in of the cheaper power. This is practically the case in Buffalo, where the transmitting company and the local companies are working in harmony. It will also be the case with the proposed transmission plant from Leavenworth to Kansas City, and other like examples could be mentioned.

That the question of rates is one of the most important before the electric light fraternity at the present time was thoroughly demonstrated by the interest aroused by the papers of Messrs. Wright and Cahoon, the discussion of which extended over two sessions of the convention. If we understand aright the remarks that were made during the meeting, and outside of it in private intercourse among the members, it is not putting it too strongly to say that in spite of the improvements that have been made in the last five years, the matter of rates in the average American central stations is in little better state than that of chaos. Mr. Cahoon struck the keynote when he stated that most small stations could not continue to exist if they were deprived of their public lighting contracts, and as this statement was not denied or controverted in any way, it is safe to assume that it is frequently the case. Of course this does not apply to the big stations in populous localities, but rather to the small ones in cities not exceeding thirty to fifty thousand inhabitants. That this should be the case after nearly twenty years of life in an industry on which so much money and ingenuity has been lavished is a reproach to American financiering and engineering ability. Of course it must not be forgotten that many stations are suffering from the fact that they are obliged to operate early types of apparatus, working at low efficiency for only short runs, but Mr. Wright contends that the root of the trouble lies in the methods adopted for charging for current. We need not enter into the details of Mr. Wright's arguments, as these are fully given in his paper appearing elsewhere in this issue, but we recommend this paper most heartily to the consideration of all interested in central station management. That Mr. Wright's views are in the main correct there can be no reasonable doubt. If the exact methods employed by him are carried out, or others tending to accomplish the same results, it must stand to reason that a revision of rates must be undertaken by the majority of the central stations in the United States, if they would hope to survive the onslaughts of the gas interests.

And this brings us to a point raised in the discussion of Mr. Wright's paper, in which one of the most influential members insisted that it was wrong for electric light stations to attempt to go under the price of gas; all that was necessary or desirable, he contended, was to meet gas on equal terms, and no more. If ever there was a false and pernicious doctrine promulgated in electric lighting circles, we think that doctrine deserves to be so characterized. The supply of electricity, so far as the public is concerned, differs in no way whatever from that of gas, water or any other commodity for which the public has granted franchises to the companies providing them, and it is safe to say that the same public will always seek to obtain those commodities at the cheapest rate at which they can be produced. Take the case of New York City, in which only within the last month the State Legislature has compelled a reduction in the price of gas from $1.25 to $1.00 per thousand cubic feet, the reduction to be made gradually over a period of five years. Does anyone suppose that if it could be successfully demonstrated that an electric light company were making enormous profits it would be allowed to maintain high rates for the sole purpose of keeping above gas rates and permitting the general manager to stand in good favor with the stockholders? We think not. What electric lighting companies want to do, above all, is to reduce their rates to the lowest point at which they can be maintained and afford a fair profit to those who have invested their money in the enterprise. The public has unquestioned rights in the premises, and experience has shown that it will exercise them when it believes them to be infringed. We are exceedingly glad to know that this matter of reducing rates to the lowest possible limit, consistent with a fair profit, is recognized among some of the largest and most prosperous electric lighting companies in the country, notably New York, Chicago, Boston and Philadelphia, and that some of them can rightfully boast that their largest customers are actually getting electric lighting for less than the cost of gas. These companies are to be commended in every sense of the word, and we cannot too strongly express our disapproval of the theory that the public has got to wait on cheap gas in order to obtain cheap electricity.

Apropos of gas it came out during the discussion that what the electric lighting central stations had to fear most was the isolated plant, and that if it were a mere case of limiting the price to meet the competition of gas, the central station might shut down. Although evidence shows that the isolated plant cannot produce current cheaper than it can be furnished from a central station, yet it will probably take a long time to convince owners of large buildings that such is the case. However, we note a growing practice among owners of large buildings, even if they furnish current for lighting, to connect the building with the street mains, and sometimes to let each tenant pay for as much current as he consumes, according to the meter, paying directly to the lighting company. There is no hardship in this, so far as we can see, as the rent would, of course, be reduced in the absence of current for lighting, while on the other hand each tenant only has to pay for exactly the amount of light consumed by him, which he can easily regulate.

The report of the committee on data was limited, so far as the number of central stations reported is concerned, to a little more than a baker's dozen. It nevertheless makes good reading, and points out some facts which are not as well understood as they ought to be. It shows, of course, that the weak end of every steam-driven station is the engine and boiler, and more particularly the engine. It will be noted that the best showing made is 3.71 pounds of coal per kilowatt hour, or 269.5 watt hours per pound of coal. It is needless to say that in this case the engines are compound condensing direct connected to the dynamo. There are probably few stations that can equal this showing, but it indicates the point that can be attained when both the mechanical conditions and the conditions of the load itself are favorable. Taken in connection with the interesting chart of the losses which occur in a steam central station, published as a supplement to our last issue, the reasons for the showing made by most stations are not difficult to discern.

VACUUM TUBE LIGHTING.

COMMENTING on the exhibition of vacuum tube lighting made by Mr. D. McFarlan Moore, the "Electrical Review" in its last issue states that, as it "predicted" a year ago, "the vacuum vibrator has been abandoned; a rotary device is now adopted which, we believe, will meet the same fate;" and it expressed its further belief "that practical and competitive lighting by the Moore system is a problem far from being solved." Every one is entitled to his predictions, beliefs and opinions, and it has never been our object to champion Mr. Moore's or any other inventor's work specifically, but we take most emphatic exception to the implication conveyed by our contemporary's remarks that Mr. Moore has made no progress in his work during the past year. Any one who had special facilities for observing the action of Mr. Moore's vacuum vibrators a year ago, which it is only truth to say, required more or less attention, expected advances, but the exhibition given two weeks ago, in which a rotary vibrator was employed, must have satisfied most people that a pronounced improvement had been made by Mr. Moore in the abandonment of the vibrator and the adoption of the rotary interrupter in its place. Our hopeful views will be confirmed by any one who has had similar facilities for observation. As to whether "practical and competitive lighting by the Moore system is a problem far from being solved," that is a matter of opinion purely. We have expressed our belief that the Moore system is in at least as good practical commercial shape as the Edison incandescent system was in 1880, and we still adhere to that opinion. The incandescent art itself would have failed if it stood at the 1880 standpoint. From what we have seen we believe that to-day Mr. Moore could take a contract for vacuum tube lighting and carry it out in as workmanlike a manner as were the contracts carried out on the Edison system at the time mentioned. At any rate we have seen enough to convince us that if Mr. Moore does not solve the problem of vacuum lighting, somebody else will, and not in the far distant future either. It is, indeed, poor encouragement to designate as futile the work of an inventor who for an hour and a half continuously lights up an apartment with a pure, bright, cold white light, representing the results of several years' labor. Many another has reaped fame and fortune on a less successful demonstration than that given by Mr. Moore. If we did not encourage Mr. Moore, or any other inventor giving his life work to improving the art, we should be derelict to duty. We cannot satisfy ourselves with the gentle process of damning with faint praise. New industries are not built up that way.

GAS ENGINES FOR ELECTRIC LIGHTING.

IN a recent issue we drew attention to the abandonment of gas engines in favor of steam in the Coatbridge, Eng., electric light station. There were several circumstances connected with the operation of this plant which may be considered out of the usual run, and we expressed the opinion that the incident by no means warranted the conclusion that gas engines are entirely unsuitable for electric light work. That we were not misled in this assumption is shown by a communication appearing in the last issue to hand of the London "Electrician," in which a correspondent gives the results of the working of a gas engine plant of the Midland Railway Company at Leicester. This is a 250 h. p. plant, with 75 h. p. in reserve. The gas is produced in Dowson generators and costs only .205d. per unit as against 2.545d. at Coatbridge, or less than one-tenth, with coal at Leicester costing 16s. 6d. per ton, as against 18s. at Coatbridge. Even allowing for light loads at Coatbridge, the difference is more than remarkable. It must be acknowledged, however, that even at Leicester the cost for repairs is 25 per cent. greater than that for fuel. As regards American experience with gas engines we printed last week a contribution giving the results of a several years' working of gas engines in the Hamilton, Ohio, electric lighting plant. So far as the operation of the gas engines is concerned the result has proved so satisfactory that the gas engine plant is to be enlarged; while as to cost of fuel, that item is apparently satisfactory, due, of course, to the fact that the gas is produced by the company on a large scale. Nevertheless, the testimony, so far as it relates to the working of the gas engines as such, is of value and goes far to strengthen us in the opinion expressed on the issue above referred to, that the gas engine is not by any means out of the running.

THE TWENTIETH CONVENTION OF THE
NATIONAL ELECTRIC LIGHT ASSOCIATION
NIAGARA FALLS, N.Y. JUNE 8-9-10-1897

THE twentieth convention of the National Electric Light Association was held at the International Hotel, Niagara Falls, N. Y., on June 8, 9 and 10, with an unusually large attendance and great success.

Among those in attendance at the convention were the following:

BIRMINGHAM, ALA.—J. M. Bradley.

BELGIUM.—ANTWERP.—Louis Schaffer.

MONTREAL, CAN.—John Carroll, Ernest Carus-Wilson, Prof. Chas. A. Carus-Wilson, R. S. Kelsch, Charles Morton, J. F. Rothsay, A. E. Smaill, W. M. Lea Walbank.

NIAGARA FALLS, ONT.—Frank LeBlond, Banker R. Paine, W. Phillips.

OTTAWA, CAN.—John Murphy.

ST. CATHARINES, CAN.—E. E. Cary, Geo. A. Powell.

TORONTO, CAN.—F. C. Armstrong, E. B. Bigger, W. F. Johnson, John Langton, E. D. McCormack, Frederic Nicholls, Geo. W. Watts.

LOS ANGELES, CAL.—W. J. Barret, H. C. Hybro.

STOCKTON, CAL.—Frank P. Adams.

BRIDGEPORT, CONN.—W. C. Bryant, L. W. Eaton, J. B. Hubbull.

DERBY, CONN.—Robert E. Wyant.

HARTFORD, CONN.—A. D. Newton, A. H. Pease, C. L. Tolles.

NEW BRITAIN, CONN.—T. H. Brady.

NORWICH, CONN.—Samuel Hurlburt.

STAMFORD, CONN.—A. J. Purinton.

WATERBURY, CONN.—John E. Sewell, A. M. Young.

ENGLAND.—Mr. Magden, Mr. Reason, Mr. Arthur Wright.

ATLANTA, GA.—T. J. Harper, Geo. Sandt, W. E. Moore.

SAVANNAH, GA.—T. P. Keck.

DUBUQUE, IA.—Horace Torbert.

RED OAK, IA.—A. M. Miller.

CHICAGO, ILL.—E. H. Allen, W. L. Arnold, Maurice Coster, Fred DeLand, L. A. Ferguson, J. Holt Gates, Edw. R. Grier, Thos. C. Grier, F. S. Howard, Samuel Insull, M. J. Isaacs, Joseph Kittlestrings, W. A. Kriedler, W. W. Low, W. B. McDonald, Geo. A. McKinlock, Chas. F. Medbury, F. L. Perry, J. A. Radford, C. A. Ross, R. A. Swain, F. S. Terry, C. D. Wilkinson, C. H. Wilmerding.

JACKSONVILLE, ILL.—J. P. Doan.

PEORIA, ILL.—G. A. Schaefer.

ST. JOSEPH, ILL.—C. E. Roehl.

ELKHART, IND.—John C. Boss.

EVANSVILLE, IND.—C. P. White.

FORT WAYNE, IND.—C. S. Knight, J. J. Wood.

INDIANAPOLIS, IND.—C. C. Perry, G. O. Rockwood, Evans Woolen.

JONESBORO, IND.—R. E. Lucas.

PERU, IND.—F. D. Covington, D. A. Schutt.

WABASH, IND.—F. W. McNamee.

NEW ORLEANS, LA.—Wm. von Phul.

BALTIMORE, MD.—E. F. Baker, W. H. Harding, W. H. Lundell.

BOSTON, MASS.—Jas. I. Ayer, M. H. Baker, Comr. F. E. Barker, Wm. Brophy, H. H. Brooks, Jas. Bradley, A. R. Bush, Geo. W. Davenport, Chas. B. Davis, Comr. Flood, R. H. S. Hale, Caryl D. Haskins, Fred. M. Kimball, J. H. Mason, H. P. Moore, Sidney B. Paine, F. B. H. Paine, Chas. B. Price, D. F. Urquhart, B. G. Underwood, Arthur Wright.

FITCHBURG, MASS.—A. H. Kimball.

HOLYOKE, MASS.—S. B. Winchester.

LYNN, MASS.—W. D. A. Ryan.

MARLBORO, MASS.—H. Bottomley.

NEWTON, MASS.—Wells E. Holmes.

NEW BEDFORD, MASS.—Geo. R. Stetson, Chas. R. Price.

NORTH ADAMS, MASS.—Frank Richardson.

PEABODY, MASS.—M. L. Livingston.

SOMERVILLE, MASS.—F. Ellwood Smith, E. S. Sparrow.

SOUTHBRIDGE, MASS.—Andrew F. Hall.

SWAMPSCOTT, MASS.—Prof. Elihu Thomson.

WALTHAM, MASS.—Thos. P. Smith.

WESTBORO, MASS.—Ralph D. Smith.

WORCESTER, MASS.—H. H. Fairbanks.

BROOKLYN, MICH.—L. W. Greene.

CHARLOTTE, MICH.—W. P. Engel.

DETROIT, MICH.—T. J. Austin, Wm. J. Harting, E. E. Philips.

FENTON, MICH.—D. W. Peabody.

HOUGHTON, MICH.—Jas. R. Dee.

MARINETTE, MICH.—G. W. Hanley.

MONROE, MICH.—G. P. Hurd.

ST. JOSEPH, MICH.—W. Worth Bean.

PONTIAC, MICH.—Chas. J. Willis.

ST. LOUIS, MO.—A. C. Garrison, J. H. Rhotehamel, Ferd. G. Schwattmann, H. A. Wagner.

LINCOLN, NEB.—Prof. R. B. Owens.

HALIFAX, N. S.—E. T. Freeman.

NEW GLASGOW, N. S.—Fred. A. Bowman.

BROOKLYN, N. Y.—W. S. Barstow, L. H. Conklin, S. K. French.

BROCKPORT, N. Y.—W. H. Roberts.

BUFFALO, N. Y.—J. O. Cushing, T. C. Frenyear, C. C. Gartland, C. R. Huntley, Mr. Maguire, C. A. Roberts, H. Stott, G. Urban, Jr.

CHATHAM, N. Y.—E. F. McCabe.

DOLGEVILLE, N. Y.—Henry J. Meyer.

ELMIRA, N. Y.—S. N. Blake.

FREDONIA, N. Y.—M. M. Benner.

LEROY, N. Y.—S. M. Wheeler.

NEW YORK, N. Y.—P. C. Ackerman, F. B. Baker, C. O. Baker, Jr., H. W. Benedict, Willard L. Candee, S. A. Chase, C. T. Child, A. B. Clements, R. B. Corey, Stephen L. Coles, W. F. D. Crane, Stephen A. Douglas, D. C. Durland, H. T. Edgar, C. E. Estabrook, M. K. Eyre, Stephen H. Goddard, J. W. Godfrey, B. E. Greene, H. McL. Harding, A. W. Harvey, Dr. W. M. Habirahaw, Wm. J. Hammer, F. W. Harrington, Alec. Henderson, Chas. I. Hills, P. H. Hoover, T. E. Hughes, W. T. Hunt, H. B. Jagoe, F. A. Johnston, W. J. Johnston, E. O. Johnson, T. Kiely, E. A. Leslie, J. W. Lieb, Jr., J. C. Lott, Geo. T. Manson, Geo. R. Macintire, T. C. Martin, K. G. Martin, L. B. Marks, Thos. I. McLeod, J. McGhie, J. T. McRoy, W. McCullough, J. P. McQuaide, E. P. Morris, A. H. Mustard, M. Nathan, D. E. Newell, W. F. Osborne, N. W. Perry, E. H. Peck, G. F. Porter, E. L. Powers, C. W. Price, Thorburn Reid, E. W. Rockafellow, A. C. Shaw, J. Sachs, E. W. Scribner, C. D. Shain, J. I. Solomon, H. A. Strauss, L. Stieringer, J. H. Astruck, G. H. Swan, H. M. Swetland, E. E. R. Tratman, W. D. Weaver, N. D. Webster, Jos. Wetzler, Jeff. Wetzler, Arthur Williams, J. P. Williams, Geo. L. Wiley, S. W. Wise, J. Harry Astruck.

NIAGARA FALLS, N. Y.—G. E. Cox, ——. Brackenridge, J. P. Devine, O. E. Dunlap, W. Caryl Ely, A. C. Hastings, F. G. Lott, E. F. Price, E. T. Price, I. L. Roberts, A. Schoellkopf, L. B. Stillwell, W. E. Tuttle.

OLEAN, N. Y.—G. Forbes.

ONEONTA, N. Y.—G. A. Lane.

ROCHESTER, N. Y.—J. A. Almstead. C. R. Barnes, Chas. F. Burns, Geo. A. Redman,

SCHENECTADY, N. Y.—Jas. M. Andrews, S. Dana Greene, G. B. Green, J. W. Kirkland, J. R. Lovejoy, C. P. Steinmetz, H. C. Wirt.

SENECA FALLS, N. Y.—N. T. Wilcox.

SYRACUSE, N. Y.—P. T. Brady, H. B. Crouse, T. J. Gorke, H. A. May, S. B. Van Rauss.

TROY, N. Y.—E. G. Bernard.

UTICA, N. Y.—M. J. Brayton, W. E. Ballda.

CAMDEN, N. J.—E. A. Armstrong, Wynn Armstrong, Walter E. Harrington.

ELIZABETH, N. J.—E. H. Stevens, M. V. Foster.

JERSEY CITY, N. J.—W. W. Ritzen.

MT. HOLLY, N. J.—Jos. H. Gaskill.

MORRISTOWN, N. J.—A. H. Lynch.

NEWARK, N. J.—Ald. John Gaffney, C. McIntyre, Henry Hayes, A. D. Page.

NEW BRUNSWICK, N. J.—A. J. Jones.

TRENTON, N. J.—Paul Lupke.

MANCHESTER, N. H.—J. B. Smith.

NEWPORT, N. H.—Wm. F. Richards, M. W. Tenny.

WOODVILLE, N. H.—Geo. E. Mann.

BEN AVON, O.—E. F. Gwynn.

CANTON, O.—H. M. Lyman.

CHILLICOTHE, O.—C. H. Juneman.

CINCINNATI, O.—Edw. K. Gillett, John I. Beggs.

CLEVELAND, O.—Thos. E. Adams, M. C. Canfield, H. J. Donds, R. C. Foster, Herbert P. Glidden, S. M. Hamill, Geo. M. Hoag, H. W. Jones, S. C. D. Johns, W. H. Lawrence, Geo. R. Lean, W. J. MacConnell, J. R. Massey, J. R. Prentiss, J. Rice, W. S. Rogers, A. D. Spear, E. Whipple.

COLUMBUS, O.—T. W. Dixon.

FOSTORIA, O.—H. A. Tremaine.

GENEVA, O.—A. F. Dickinson.

NEW PHILADELPHIA, O.—O. P. Taylor.

DAYTON, O.—A. A. Thresher.

SPRINGFIELD, O.—Jno. H. Miller.

SALEM, O.—D. L. Davis.

SANDUSKY, O.—Emil G. Shurlat.

TOLEDO, O.—W. S. Smith.

WARREN, O.—W. D. Packard.

WELLSVILLE, O.—D. W. Low.

YOUNGSTOWN, O.—E. A. Biel, B. P. Holmes.

ALTOONA, PA.—J. P. Graham, E. B. Greene.

BRISTOL, PA.—Chas. E. Scott.

EASTON, PA.—Howard Reneck.

JEANNETTE, PA.— A. E. Carrier.

JOHNSTOWN, PA.—J. W. Reeves.

McKEESPORT, PA.—F. R. Upton.

OIL CITY, PA.—W. H. Cooper.

PHILADELPHIA, PA.—S. Bilyea, C. Bragg, H. Clay, H. B. Cutter, A. V. Dee, Geo. M. G. Holman, A. H. Jones, H. Lloyd, J. Mustard, E. L. Nash, Geo. L. Peeples, J. W. Perry, J. Sigg, T. C. Smith, J. F. Stevens, T. L. Townsend, J. H. Vail, E. Ward Wilkins.

PITTSBURGH, PA.—J. McN. Bennie, J. C. Callsch, Thos. Cooper, J. S. Crider, Jas. F. Cummings, D. D. Dickey, W. K. Dunlap, W. S. Elliott, E. H. Heinrichs, C. B. Humphrey, Benj. G. Lamme, F. M. Laughlin, Chas. F. Scott, C. E. Skinner, F. S. Smith.

RENOVO, PA.—James Murphy, F. M. Noecker.

SCRANTON, PA.—G. G. Sturges.

WASHINGTON, A.—Wm. P. Wieman.

WEST CHESTER, Pa.—Jas E. Pyle.

WILLIAMSPORT, PA.—H. L. Allen.

WILKINSBURG, PA.—J. J. Jennings.

PAWTUCKET, R. I.—H. C. Adams, Jr., Henry A. Pierce.

PROVIDENCE, R. I.—Geo. E. Claflin, John I. Drake, Robt. Fessenden, Wm. C. Woodward.

NORFOLK, VA.—Jas. L. Belote, Wm. W. Chamberlain, Jno. B. Whitehead, Jr.

RUTLAND, VT.—W. Parsons.

WASHINGTON, D. C.—S. W. Tulloch.

LA CROSSE, WIS.—F. A. Copeland.

MILWAUKEE, WIS.—Thos. R. Mercein, Wm. Wilson.

Among the ladies present were:

Miss Elizabeth W. Armstrong, Mrs. C. O. Baker, Jr., Miss H. Billings, Mrs. S. L. Coles, Mrs. H. Clay, Savilla E. Clay, Mabel Clay, Mrs. H. B. Cutter, Mrs. Davis, Miss H. Douglass, Mrs. Foster, Miss Helen Frisbie, Mrs. Jos. H. Gaskill, Mrs. Gorke, Mrs. Greene, Mrs. Henry Hayes, Mrs. W. T. Hunt, Mrs. M. J. Isaacs, Mrs. H. B. Jagoe, Mrs. W. J. Johnston, Mrs. W. A. Kriedler, Mrs. Lovejoy, Miss Mae E. Mason, Miss Carrie W. Morgan, Mrs. Frederic Nicholls, Miss Charlotta Packard, Miss Lena Powell, Mrs. G. A. Redman, Mrs. Thos. P. Smith, Mrs. Swetland, Mrs. Joseph Wetzler, Miss Mary Whitall, Mrs. Young, Miss Lucy C. Young.

ELEC. ENG'R. N.Y.

NIAGARA FALLS CONVENTION, N. E. L. A., JUNE 9, 1897.
This group contains only a small proportion of the delegates and friends.)

MORNING SESSION.

PRESIDENT FREDERIC NICHOLLS called the meeting to order at 10:45 a. m., and read letters from the following, extending courtesies to the association from the Niagara Falls Power Company; Niagara Falls Hydraulic Power and Manufacturing Company; Buffalo and Niagara Falls Electric Light and Power Company; the Carborundum Company; the American Telephone and Telegraph Company; from Mr. B. E. Green, rental agent, Grand Central Palace, New York. Also letters of regret from the following: Prof. Edward L. Nicholls, of Cornell University; Sir William Dawson, Magill University, Montreal; Prof. Henry T. Bovey, Montreal; and a letter of thanks from Lord Kelvin, of Glasgow University, Glasgow.

THE PRESIDENT then read his address.[1]

MR. SWETLAND then read a synopsis of the report of the Committee on Data,[2] and added that it was his belief that in future the conduct of this work would perhaps be better confined entirely to the hands of the secretary, letting him secure such information as could be obtained by correspondence, without any further expense to the association. A motion to this effect was carried and the committee discharged with a vote of thanks to Mr. H. M. Swetland, chairman of the committee.

MR. JOHN A. SEELY, chairman, then read a report of the Finance Committee, showing a balance of over $2,500 in the treasury of the association, with no liabilities. He gave notice to the chair that he would move to change the by-laws to the effect that the retiring presidents shall all become honorary members of the association.

A recess was taken till 2:30 p. m.

ARTERNOON SESSION.

On reassembling the president read a letter from the Erie Gas Engine Company, inviting the association to send a committee to Erie, Pa., for the purpose of testing and reporting upon the efficiency of the company's gas engines, as well as those of other manufacturers.

PROF. R. B. OWENS, of the University of Nebraska, then addressed the association, inviting it to hold its next convention at Omaha, in connection with the Trans-Mississippi Exposition.

MR. EVANS WOOLEN invited the association to Indianapolis, Ind. Both invitations were referred to the Executive Committee.

MR. J. B. CAHOON, of Elmira, N. Y., then read his paper entitled "The Establishment of a Base Price for Current."[3]

MR. CAHOON added that with regard to the superintendent's monthly report that was a sort of a cosmopolitan thing obtained from working over the reports of about sixty different stations. Each man had his own particular ideas on the subject, and the only object of putting them in was to bring the subject up and see if a standard set of blanks could not be gotten up.

MR. J. I. BEGGS, of Cincinnati, stated that in a new station to be built by his company he hoped to generate as many kilowatt hours for $18,000 for what now took $54,000 in coal per annum. Blanks should, therefore, give not only the price of coal and the quality of it, but the type of the apparatus that is being used, as well. Some of the larger stations in the country, and particularly those supplying current from the Edison three-wire system, have agreed upon and adopted uniform sets of blanks whereby the distribution of the various items of expense in the operation of stations are made exactly the same, and they exchange these blanks or have them criticized from month to month. They all see what their different stations are doing; and there is nothing better calculated to bring about an improved condition of station operation.

Further discussion of the paper was deferred.

THE PRESIDENT.—The next item upon the programme is the topic for discussion entitled "Theft of Current and How to Deal with It." During the past year when I have been looking into several matters and considering lines, or directions, in which work could be done that would serve the best interests of the members of the association, I was very much astonished to find that in hardly any State of the Union was there provision made in the common law for the punishment of any person who would deliberately steal current from the street mains or otherwise. It seems to me that that is something that should be provided for. I know in Canada we have provision made for the punishment of theft of current; and it seems to me that a question of this kind should be taken up by the association, and that the different members should work together so that there could be a clause added to the criminal code of the different States providing for the punishment of this offense. Mr. T. C. Martin was speaking to me in reference to this matter this morning and had with him the draft of a law that has just been passed in one of the States.

MR. T. C. MARTIN.—The bill was brought up at the last session of the Connecticut Legislature and was referred to a committee, was approved and returned to the Lower House and passed, was sent up to the Senate and was passed there; went through both Houses, I understand, with very little opposition from any quarter; and within the last ten days, I think, the bill has received the assent of the Governor and I presume is now part of the law of the State of Connecticut. There is a small money fine attached to the offense, or a short term of imprisonment. The bill seemed to me weak in regard to the requirements as to the proof of theft. Whether that feature has been improved in the bill as made law, I am not able to say. I had some conversation not long ago with Mr. Russell B. Harrison, who had encountered the difficulty of theft of current at Terre Haute, and I found that, although the cases were pretty well proved, he had hesitated to bring action because he was advised by his lawyers that under the existing state of the law it would be difficult to secure a satisfactory conviction within the law as it then stood. There have, however, I believe, been one or two other cases, among them one in Louisville, Ky.

MR. J. I. AYER moved that a bill be drafted by the association which would meet the requirements of the offense, and that it be uniform in the different States.

MR. YOUNG, of Waterbury, Conn., stated in relation to the law that has just now been passed in Connecticut, it happened to be his duty as treasurer of the Connecticut Electric Lighting Association to have this particular bill drafted, and it was drafted by the attorney for their association, and it passed, as Mr. Martin had stated, without any serious opposition through the Legislature and had been signed by the Governor. The penalty attached is a fine of $50 and imprisonment for ninety days, or both.

MR. STETSON.—If it is thought well to appoint this committee, I might say it would be well to examine the law that is in force in Massachusetts. Last year or the year before the law was made to apply to the theft of current the same as to the theft of gas; and it gives me pleasure to report that a man that had ordered out his meter and had put in wire to occupy the space that the meter previously occupied and had gone right on in the lighting business, was brought into court and it cost him $55 to get about 50 cents' worth of electricity.

COM. BARKER.—Mr. President, I do not think I can add anything to what Mr. Stetson has said. The law, I think, was promoted by the efforts of the Massachusetts Electric Lighting Association. It was passed by the Legislature with practically no opposition, and perhaps the passage of the law was aided by the fact that a law prohibiting such theft of gas had been upon the statute books for a number of years. I think the courts in our State have held that it is not a common law offense to purloin gas, and therefore they would be likely to hold in the same way with respect to electric current; but the statute seems to be a sound one. I think there have been a number of prosecutions successfully carried out under it in our State—if I mistake not, in the city of Lynn. It has been in existence for a couple of years and is modeled after the act which prohibits and punishes the theft of gas; and I think the general opinion is that it is a good law.

MR. MARTIN.—Mr. President, Mr. Stetson's suggestion moves me to believe that perhaps it would be a good thing if I could supply the omission of bringing the bill with me by placing it in the hands of the official stenographer. That would make it a part of the transactions, and in that way it would very quickly reach a great many members of the association who are not here and other electric lighting men throughout the country who are very much interested in this question, as I know from the number of letters that I have received on the subject. Cases of theft seem to be getting daily more numerous, and now that we are threatened with the application of it in large quantities for the purpose of burglarizing safes, it seems to me perhaps it would be well to protect ourselves before that new industry gets upon its feet. (Laughter.)

---

[1] See page 671.
[2] See page 664.
[3] See page 669.

W. P. ENGEL, of Charlotte, Mich.—Mr. President, with your permission and that of the members, as I am not a member of this association, I would say that legislation has been inaugurated in the State of Michigan, upon this subject, through the efforts of several central station men, and the Municipal Light and Power Company, of Grand Rapids, sent out a circular which embodies a law called House Bill No. 955, Legislative Session of 1897. That law embodies punishments, and it also includes gas, water and electric current. I have a copy of it and if a committee is appointed I will deliver this to them that they may look at it; or it may be read if you so choose.

MR. BEGGS.—I have been instrumental in having one conviction brought about in the city of Cincinnati, although the Ohio law is somewhat indefinite upon the point. We could only proceed under the law that was passed for tapping wires, for an entirely different purpose. But this case was so clear that we brought the action. Our principal difficulty is tampering with the measuring instruments themselves; not so much tapping the wires, taking the current direct. Therefore when a bill is drawn it seems to me it ought to be broad enough to cover every condition in which a man attempts, not only to steal current but in any way to tamper with the instruments that are employed for measuring, and which is the most prolific source of loss to the central station. In the case I referred to we prosecuted the man, and, I believe, he was subjected to a fine of $50. But our greatest difficulty was to have the grand jury even bring in a bill against him because of his political pull. But it was a saloon in which we never even had furnished the current. He had been cut off for nonpayment of bills by one of our competitors. Our lines happened to cross near the rear end of his premises. He threw out a grappling hook and got connection on there and lighted himself for several months in that way. There was really no law applicable in the State of Ohio unless we prosecuted him upon the charge of tapping wires, under a law that was passed for the protection of race courses and things of that kind.

MR. CLAY.—I fail to see how a committee would accomplish any satisfactory results to the members of this association, owing to the fact that the conditions differ in the various States of the Union. Two years ago we put upon the statutes of Pennsylvania a law which makes it a misdemeanor punishable on conviction by fine and imprisonment for any person to take current or in any way interfere with electrical apparatus.

JUDGE ARMSTRONG.—From what has been said in relation to the various laws that have been passed I judge that the penalty is grossly inadequate. You know there is an old adage, where there are twelve lawyers there are thirteen opinions always, but I am strongly under the impression that if a grand jury should return a bill of indictment for larceny to my court against a man for tapping a wire and taking power, and the jury believed that he had done it, I should not hesitate to sentence him for larceny under the law as it now stands. There is nothing in our State that I recall, no decision of the Supreme Court, that would prevent that thing. This Michigan proposed bill, and the one in Connecticut, makes it a slight misdemeanor only. If a man steals above $30, I think it is, it is grand larceny and he may be imprisoned for from two to five years, depending on the circumstances. Here three months, and $100 is the maximum penalty, in this bill. In the Connecticut bill it was $50. I want to protest as strongly as I can to this association against their recognizing by anything they do the propriety, if I may say so, of anybody taking electric current the same as they would take in sunlight or take in air. That has been the idea upon which they have acted heretofore; and we may by any act that we do give a good deal of credit, a good deal of strength, to that. Judge Armstrong described the methods adopted by his company to educate the intelligent public in the idea of the cost of producing current for use.

THE PRESIDENT.—It has been moved and seconded that the chair appoint a committee of three to prepare a report upon this subject and draft a bill which would be uniform and apply to all the different States; and the mover of the resolution also suggests that so soon as that report be drafted that it be forwarded to each of the members of the association. Is it your pleasure that the motion be declared carried? (Carried.)

THE PRESIDENT.—The convention ordered this morning that the report of the Committee on "Rules for Safe Wiring," Capt. William Brophy, chairman, should be presented this afternoon. I now call upon Capt. Brophy, as chairman of the committee, to present his report. The report was read.[1]

CAPT. BROPHY.—I believe I was one of the original members of the conference first held at Capt May to bring about this result. I have been a member of this committee from that time on. I have labored faithfully to bring about this end. Sometimes, as I have described here, the task seemed almost hopeless, but I never was ready to sacrifice the right of the men engaged in the electric business to have their say in the formation of rules under which they were obliged to install their apparatus. As I said before, I have given both time and means to bring about this end. I hope to see it consummated; then I shall be satisfied and consider my task done. (Applause.)

MR. AYER described in detail the arduous work of the committee of which he was a member, and particularly of Captain Brophy and Mr. W. J. Hammer. He urged immediate approval by the Association of its own work now presented.

MR. CARNES moved the adoption of the report. Seconded. Carried.

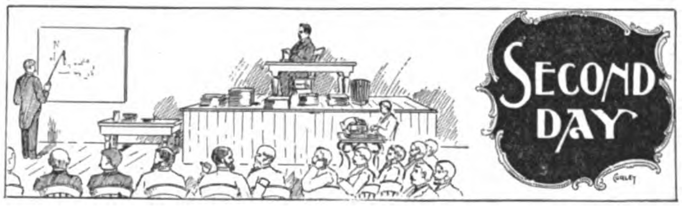
THE PRESIDENT.—The next order on the programme is a paper on "Municipal Lighting," by Mr. W. Worth Bean, of St. Joseph, Mich. I will call upon Mr. Bean to read his paper. The paper was read.[1]

MR. DOUGHERTY.—I consider this subject a very, very serious one. I am out of the woods myself, but I have had a little experience in it. Mr. Bean has, and several other members. I think it is a matter that would warrant the attention of this association—their continued attention, rather; and the portion referring to the data furnished, except by sending a representative to the plant, I wish still further to corroborate. I have had a little experience in that as former chairman of the Northwestern Electric Association. The city plants now in operation are, many of them, a dismal failure, but every one of them sends out reports that look very inviting to other cities. I merely rose to urge that although the paper may not have a great deal of discussion, the members treat it seriously and continue the protection in this line that the association has already endeavored to provide.

MR. BEGGS.—The remarks of Mr. Dougherty prompt me to suggest, taking a text from the president's remarks this morning, that he didn't think it was necessary for an association of this kind to have a large surplus fund. It seems to me that there is no use to which the association could devote a part of those funds with greater advantage to the central station and lighting interests of the country than to employ an intelligent, painstaking expert to get reliable data from a number of municipal plants in different sections of the country. As has been well stated in this paper, the data that is available, except in very few cases, is unreliable in the extreme. Mr. Beggs went on to urge the employment of an expert to get and analyze some of the municipal plant figures.

THE PRESIDENT appointed Mr. Ayer as the mover, Judge Armstrong and Senator Foster S. Voorhees, of Elizabeth, as members of the committee to draft a law providing for the punishment of the theft of electric current.

An invitation was read to take the next convention to Old Point Comfort. Referred to Executive Committee. The meeting went into executive session and then adjourned.



MORNING SESSION.

PRESIDENT NICHOLLS in the chair.

THE PRESIDENT introduced Mr. J. G. White, of the White-Crosby Company, New York, who read a paper on "The Niagara Power Transmission Line."[2]

MR. SEELY inquired whether it was necessary to shut off the current when replacing insulators.

MR. WHITE.—Some insulators have been changed without shutting down, and it is quite practicable to do that where the wire has not been tied in. Where it has been tied in, unless on a very dry day, I should rather somebody else would attempt to replace the insulators with the current on. But I know of other 10,000-volt lines where it is done, and by having a large stool mounted on four porcelain insulators on which a ladder can be placed, it will be entirely possible for a man to get up to the line and replace the insulator. The only trouble about that is that with 10,000 volts the capacity of a man is sufficient to absorb considerable spark, and if the man was nervous he might get shock enough to knock him off the ladder. So it is not a pleasant task, but it is entirely possible. We did replace a number of insulators where the wire had been tied by lifting the wire on the top of another insulator which was mounted on a long stick and then replacing the insulator and letting the wire come back into place. In actual construction the wire, as you probably know, was not placed at the corners of a triangle, but the line was divided into six sections, and at five points three wires were given a twist, so that for two of the six sections each of the three wires occupied relatively the position of 1, 2 and 3, and this counteracts to a considerable extent the induction which would otherwise be exerted. I should say that under all circumstances where it is possible, unless the right of way cost too much, or is too expensive, trees ought to be cut 30 or 40 feet on each side of the line, and more if possible.

---

[1] See page 672.

[1] See page 655.
[2] See page 674.

MR. SEELY.—I presume time only will demonstrate the efficiency of the 30,000 or 40,000-volt tests applied to the insulators?

MR. WHITE.—There is no data as to that. But the mere fact that not a single insulator has broken down during this time is pretty good evidence. With the other insulators which were put up temporarily, the depreciation on the line was quite rapid, as mentioned in the paper. We used to have cross-arms burn off quite frequently, and that came from the fact that although these insulators had stood that 20,000-volt test, and there was only 10,000 on the line, yet enough rain would strike them to gradually moisten the porcelain, and, of course, as they absorbed this moisture the insulating properties would drop down to so small a value that they allowed the current to go through until it burned off the cross-arms from the arc that would form. That, of course, would break the contact and the arc would stop of its own accord. The brim on the helmet insulator had not yet proved to be of much importance in shedding the rain as it was hoped. The lightning arrester problem is still in the process of being solved. There are very few of them on the line. The line is protected as much as we could from lightning by running two barbed fence wires on top of the poles, one carried on the outer cross-arm by an iron pin 18 inches long and 1 inch in diameter, which went through the cross-arm and had a little fork at the top supporting the barbed fence wire. A second similar wire was carried on the peak of the pole, the poles all being roofed, and a third is intended to be put up on the other side of the cross-arm when additional wires are put up. Every fifth pole these barbed fence wires are grounded with a No. 6 copper wire running to the bottom of the pole and being coiled there, so that we can expect discharges will be carried off by these numerous points without accumulating sufficiently to give a lightning stroke. But the lightning arresters themselves are placed only at the transformer houses up to date, and those have given some trouble; so that probably none will be placed on the line until something has been put in the transformer houses that is perfectly satisfactory.

MR. SEELY.—I would assume that it would be preferable to place the wires underground entirely. It would cost probably, according to your figures, about $800,000, or $40 per h. p., and would be free from the defects of the overhead wire.

MR. WHITE.—That view, of course, is possibly correct. But as I stated it has not been demonstrated up to date, from the fact that the only trouble due to the line so far was from a joint in the cable. There is no trouble due to the insulator; and there are 4,000 feet of underground as against over 24 miles of insulators; so that we have about thirty-five chances to one as far as distance is concerned of trouble with the overhead as compared with the underground.

MR. S. D. GREENE.—It seems to me that the question of lightning on a line is really the most serious point to be considered, as to the comparative advantages of the overhead and the underground lines. It is a fact that no tests which any manufacturing company that I know of can produce at their works are at all indicative of the results to be obtained on the line here; and it has been found actually necessary for them in testing lightning arresters and fuses to bring the experimental apparatus to Niagara Falls and actually test it by short-circuiting the machines here. In other words, the effect of a short circuit with 5,000 h. p. generators on a 10-000-volt line is very different from anything obtained in ordinary use and practice. While it is probable that the lightning protection that has now been devised in the line will be sufficient to answer the purpose for the present, yet there will always be more or less risk from lightning until the wire is put ununderground.

MR. SAMUEL INSULL.—Did I understand Mr. White to say it would cost $600,000 more for a line to carry 20,000 h. p. under ground?

MR. WHITE.—It would cost about a million and a quarter for a line carrying 20,000 h. p.; that is, four series, three wires each, making 12 wires total, for a distance of 27 miles; with lead-covered cable, of which 4-5 would be for lead-covered cable and 1-5 for conduit. That would mean $60 per h. p., and overhead about ⅓ of that amount, or $20 a horse-power. If placed underground at $60 the interest charge of course would be $3, allowing 5 per cent., and at least an additional amount equal to that would be allowed for depreciation, and probably a good deal more than that.

MR. INSULL inquired whether lightning arresters up to 1,000 h. p. would carry a lightning discharge and at the same time interrupt short circuit of the dynamos without serious trouble?

MR. GREENE thought it might be possible, but he did not think any company would guarantee such a device. Of course the network which Mr. White described as having been placed on the top of the poles was a good protection, but he did not think it was an absolute protection against lightning under all conditions of stroke.

MR. INSULL did not believe, after looking at the Niagara plant, that it could be installed for much less than $100 a horse-power. It seemed, therefore, that a long distance power transmission plant, including the underground conductors, would cost at least 60 per cent. more than the steam plant to produce the best possible results from steam in the city of Buffalo.

MR. BEGGS thought that existing plants had nothing to fear from long distance transmissions, and he questioned whether even the great Niagara Falls plant could compete with the modern steam plant fifty miles from Niagara Falls. He instanced several propositions recently submitted to him, among them one for transmitting 40,000 h. p. at 60,000 volts 60 miles.

MR. WHITE agreed with Mr. Beggs that the localities were very few and the circumstances must be very exceptional which would support a transmission line 50 miles long.

MR. STEINMETZ thought it was dangerous to generalize too freely in such matters, and to state that it is or is not economical to transmit power 50 miles. It all depended upon what the power was used for. The problem changed very greatly according to whether the power is used in a factory for 24 hours a day, a steady load, or whether it is used where the whole load is only an hour a day run and the remainder is idle, and you have to pay the same price; and other conditions.

MR. C. F. SCOTT gave the results of the successful attempts in overcoming the effects of lightning at Telluride, Colo., on a 10,000-volt circuit.

MR. WHITE corroborated Mr. Steinmetz's remarks and cited the case of Leadville, Colo., where it was found that power in some instances was costing the miners as high as $2,000 a horse-power for the actual indicated horse-power on a hoist. In such a case as well as at Cripple Creek power might be transmitted 50 miles at a profit.

MR. W. L. WALBANK.—We have just constructed a steel pole line from Lachine Rapids into Montreal. We took a channel iron and cut it diagonally through and then riveted the reverse ends so as to make it about 8 inches at the top and 20 inches at the bottom; put two of these columns up and then latticed them together; the wooden cross-arms are almost identically like those at Niagara, but without any braces underneath, and we have altogether 36 wires on. Our poles are placed 108 feet on centers and they stand probably 30 feet high, including 7 feet in the ground. They are bedded 7 feet in concrete. Our pole line complete, with wire, insulators, cross-arms and everything, will cost us for a distance of 30,000 feet, for the complete line, about $92,000. We figured that for underground work it was going to cost over $300,000, to do the same thing with lead cable. We have not tested it practically yet, because it is just about completed now.

MR. ARTHUR WRIGHT, of Brighton, England, then read his paper on "Profitable Extensions of Electricity Supply Stations."[1]

In the discussion, Mr. Wright, in reply to a question stated that the whole of the plant at Brighton, England, is direct connected, and in the years analyzed in his paper there was no condensing plant. His longest transmission line was two miles from the station. The least price for a kilowatt hour is 14 cents; the price for extra hours was 3 cents per hour for every additional hour. The average income per kilowatt hour this year will be 6 cents. Gas sells at 66 cents per 1,000 cubic feet. In reply to a question by Mr. Beggs, Mr. Wright stated that his most favored customer was paying 3½ cents per kilowatt hour.

MR. J. I. BEGGS stated that this was cutting the price of gas in two, and that it was a great injustice to the small consumer. He never felt that electric light companies ought to cut under gas. He merely tried to bring it down to the price of gas. He believed the greatest menace to central station companies was the isolated plant. In the companies with which he is now connected he had opened an account whose technical ledger title is "depreciation, reconstruction and reserve," to which a certain amount of money is carried monthly as a liability of the company, and the funds kept in hand for use in the years to come when either present installations may become antique or some unforeseen circumstances arise whereby the company would have the means to put themselves in position to compete with the advances made in either the production of gas or more modern lighting plants.

---

[1] See page 656.

MR. SAMUEL INSULL.—I am running a company that is operating on the Wright demand system in practice, but not in theory. As Mr. Beggs pointed out we have to compete with the isolated plant, and I assure you that if you are going to assume that the lowest price you can charge for electric current is the price that is at present charged for a unit of light by the gas companies of this country you cannot compete with incandescent isolated plants. I can show you cases where you have got to go as low as 6, or 5, or 4½ cents per kilowatt hour, if you are going to compete with the isolated plant.

MR. INSULL advocated the differential rate of Mr. Wright and gave examples of its necessity. As regards a remark of Mr. Beggs that his basis of discounts gets over the difficulty, that was not so. Thus, he referred to one building where, if bills were rendered against the owner of the building stead of the tenants, they would be entitled to the biggest discount. It is the largest building in Chicago; and yet, as a matter of fact, it was not very profitable business at 20 cents per kilowatt hour. On the other hand, a man who has a comparatively small store, and who pays just about the same amount per annum, has a business which is ever so much more profitable at 70 per cent. off 20 cents a kilowatt hour, or 6 cents a kilowatt hour.

MR. STETSON fully indorsed the desirability of the plan devised by Mr. Wright, and, with Mr. Insull, believed that by its adoption the smaller companies would no longer have to look for their profit to the city contract.

MR. FERGUSON criticised Mr. Wright's plan in that it made no distinction in regard to the time of day on which that maximum load comes.

MR. WRIGHT, in reply, stated that all these standing charges were not hourly, monthly or daily charges. They were an entire charge against the whole investment, and if you had an installation taking current before six o'clock, and another equal installation taking current after six o'clock, both these installations ought to pay half of the necessary investment charges, and not one.

In reply to a question by **DR. FENNER**, as to just how the Wright system was worked in practice, **MR. WRIGHT** said: There is an instrument put alongside the ordinary meter. This instrument tells the station manager and the consumer how much per annum he must pay the company to pay off the charges for getting the plant ready. The ordinary meter shows him the total bill. The other is what we call the demand indicator. The meter shows the total amount of electricity consumed and the demand indicator tells him by direct inspection how much of that electricity has to be charged at a high rate, and all the balance at a low rate, in order to make him profitable. The instrument does it without calculation. Mr. Insull had stated that it might be possible to do this without an instrument, but he thought the cost of doing that would be exceedingly great.

DR. FENNER.—Do you vary this 14-cent per k. w. hour initial charge in accordance with whether it is all done in an hour or whether it is spread over the 24 hours?

MR. WRIGHT.—Yes. When we first started it, we charged 14 cents for two hours per day, or 730 hours per annum. As we got larger the standing charges in proportion diminished. Then we diminished the time during which it was necessary to insist on the high charge.

After some additional remarks by **MR. S. D. GREENE** and **MR. FERGUSON** the further discussion of the paper was deferred until the afternoon session.

A letter was read from Mr. H. H. Littell, vice-president and general manager of the Buffalo Railway Company, inviting the delegates to visit the power house of the company, on Niagara street, Buffalo.

AFTERNOON SESSION.

PRESIDENT NICHOLLS called the meeting to order at 3 p. m., and read a letter from Mr. W. Caryl Ely, president of the Buffalo and Niagara Falls Electric Railway, inviting the delegates to an excursion on special cars, from Niagara Falls to Tonawanda and return. Also a letter from Mr. Wm. H. Brown, of the Royal Electric Company, Montreal, suggesting Montreal as the place of the next convention of the association.

The discussion on Mr. Wright's paper was then resumed, and by request, **MR. RAWSON** gave a brief description of the Wright demand indicator as follows:

The instrument which we are now using, is really a differential gauge adapted with various modifications, so that we really have a thermo self-recording ammeter, or what we may practically call an ammeter, that shows at a glance the maximum demand that the consumers have made upon the station. The index is non-returning and liquid; consequently we lose nothing. The delicacy of the readings is very great.

I should just like to mention one or two points in connection with my own personal experience with this instrument as being used in other cities besides Brighton. We have the instrument now in use in 40 cities in the United Kingdom; and certainly in more than one case it has turned non-profitable companies into dividend paying companies. I refer more particularly to Northampton, Eng., and Preston, Eng. In both those cases the companies had been operating for some three or four years in a very disheartening way. I think I am safe in claiming that as a recording ammeter there is nothing that can be obtained so cheaply. There was the question raised this morning as to whether our experience at Brighton, which Mr. Wright set forth, really, last year, yielded a profit at all. Now, last year at the central station in Brighton, in addition to the setting aside of a sum equal to 5½ per cent. of the whole capital for depreciation and redemption, which is really a dividend of itself according to the ideas of a great many managers, we, in addition, earned nearly £6,000 net; that is to say, nearly $30,000 net on a capital of $200,000, or an extra five per cent. over that first 5½ per cent. That, I think, puts that question clearly. In Brighton, Eng., we averaged on our tariff something over nine cents per kilowatt hour right through, surely we are friends of consumers; and if we made, as we did last year, the profit I have told you about, surely we are the friends of central station managers. The smaller central stations in England were very glad to welcome us. Those of the large districts of London have adopted the Wright system, and we have also the City of Glasgow, in Scotland, which is our next largest city. The big industries, of course, do say, "Well, while we are doing well let us alone"; but I submit to you, gentlemen, who are in control of large stations that the security of that prosperity must surely be based on your answer to the dissatisfied customer. We make our instruments and calibrate them absolutely to read directly in kilowatt hours. Give us your fixed charges, give us your lamps, on the other hand, and we will tell you what the tariff ought to be.

The speaker then referred to the flat rates in vogue among telephone companies, which included the stand-by charges. Also to the practice among livery stable men to charge more for the first hour than for subsequent hours. The speaker declined to admit that gas was an ideal in any shape or form, except for heating, and that it had any right to arbitrarily define what is the proper basis for electricity supply. That being so, he wished to point out that on a flat rate one must always make the good customers pay for the bad; that was commercially inexpedient and theoretically and absolutely wrong. The first thing his friends and he saw on landing in this country were gasoliers provided with electric lights, but the electric lights were out,—because they didn't land until half past eight; the same as in the large English cities. In Brighton they had improved the load factor; that is to say, the earnings per horse-power demand at the station were something like 45 or 50 per cent. The cost of installing the Wright instruments did not come at more than two or three per cent. on the whole of the capital.

The next paper read was that by **PROF. CHARLES A. CARUS-WILSON**, of McGill University, Montreal, entitled, "The Induction Factor; a New Basis of Dynamo Calculation and Classification."[1] Prof. Carus-Wilson added that he was much indebted to the General Electric Company for this data, and that he would be glad to correspond with the members on the subject of his paper.

The president then introduced **PROF. ELIHU THOMSON**, who read his paper on "Recent Progress in Arc Lighting."[2]

MR. T. C. MARTIN'S paper on "The Daylight Work of Central Stations" was read by title.[3]

The meeting then went into executive session.

MR. F. W. JACKSON, the secretary of the San Diego, Cal., Gas and Electric Light Company, says: "Each issue of The Electrical Engineer is replete with articles of the highest interest and value to anyone engaged in the electrical industry."

---

[1] See page 667. [2] See page 662. [3] See page 660.

MORNING SESSION.

PRESIDENT NICHOLLS called the meeting to order at 10:30 a. m., and introduced Mr. B. F. Lamme, of Pittsburg, Pa., who read his paper on "Polyphase Motors," discussion on which was postponed.

The meeting went into executive session.

AFTERNOON SESSION.

PRESIDENT NICHOLLS called thte meeting to order at 2:30 p. m., and called upon LIEUT. F. JARVIS PATTEN, of New York, to read his paper on "Frequency Transformation."

This was followed by that of MR. CHARLES F. SCOTT, of Pittsburg, Pa., entitled "Rotaries for Transforming Alternating into Direct Current."

MR. J. I. AYER then read the report of Committee on Standard Candle-Power of Incandescent Lamps.[1]

MR. AYER.—I will state in connection with this report that the idea is to have a form of incandescent lamp specified which may be produced by the different manufacturers without identification marks, and submitted to the secretary; these in bulk to be turned over to some college testing laboratory; the test to be made under the supervision of the non-partisan committee of the association and of the Institute of Electrical Engineers. As to the photometer arrangement, it is proposed to make a specification of a photometer, which would cost little, which would be handed over to different manufacturers, and when made would be submitted to this committee as to its approval. This puts the central station man in a position to have a photometer which can be easily operated by any ordinarily intelligent station employé.

MR. INSULL moved a resolution that the report of the committee be accepted, and that their recommendations be adopted by the association, and, if necessary, that the committee be continued. Carried.

On motion, the secretary was instructed to prepare the customary resolutions for the retiring president.

MR. AYER called attention to the matter of freight classification on electrical merchandise, which, he said, was all out of reason; that is to say, there is no discrimination. Thus one might ship a dynamo frame with no wire on it, just a simple piece of casting, and yet have to pay on it as electrical merchandise at double first-class classification. He moved the appointment of a committee to take this matter up with the chairman of the Traffic Association, with a view of revising the freight rates. Carried.

THE PRESIDENT then referred in fitting terms to the loss sustained by the association in the death of Messrs. H. J. Smith and J. M. Orford.

The convention then went into executive session and adjourned sine die.

MR. STILLWELL'S N. E. L. A. LECTURE ON NIAGARA POWER.

On Wednesday evening Mr. L. B. Stillwell, director of the Niagara Power Company, delivered a lecture entitled "Niagara Power" in the pavilion of the State Reservation.

The lecturer introduced his subject by showing how every utilization of the forces of nature made for civilization, and affected the social conditions of mankind for the better. Coming to the power of Niagara, he stated that the average output of fifty men working continuously is equivalent to 1 h. p. The power which the whole human race could exert, would, therefore, about equal that represented by the Falls of Niagara. Niagara, in fact, was a solar engine, every pound of water above the rapids representing 200 foot-pounds of energy, the entire falls being equal to 5,800,000 h. p. To produce an equal amount of power by steam would require 13,000,000 tons of coal per annum, equivalent to about one-third the total coal output of the world. To put it in another way, Niagara could supply 3,000,000 arc lamps, or 600 generators such as those installed by the Niagara Power Company, having a capacity of 65,000 incandescent lamps each. Of the total power of the Falls, about 4,000,000 h. p. could be delivered to turbines, and of this about 3,000,000 would be available in practice.

Mr. Stillwell then gave a brief sketch of the plans which were originally considered for distributing the power, the methods being, shafts, cables, hydraulic, and compressed air transmission, and electricity. As the lecturer aptly put it, the mediums of transmission considered were of four kinds, namely, by solid, liquid, gas and ether in a state of strain; that is, from the material to the immaterial. The numerous advantages of electric transmission had led to the choice of that method. The lecturer emphasized the fact that the Niagara Power Company was building not only for the present, but for the future.

A large number of lantern views were then thrown on the screen, which illustrated the dynamos, turbines and other details of the great power house at Niagara Falls.

SECRETARY G. F. PORTER has, it was learned at the convention, accepted a very responsible position with Mr. Brixey in the Kerite wire and cable business, but owing to the irresistible pressure brought to bear upon him from every quarter has consented to hold office for a while. He hopes to issue the current volume of proceedings in very quick order. If any association has ever had a better secretary than Mr. Porter, history has failed to record his name.

ONE DOLLAR was the small sum for which the association issued a coupon book full of double passes or "return trips" for all the leading attractions around the Falls, representing a saving of nearly $2 to every purchaser. Some three hundred coupon books were sold. The hackmen were remarkably moderate in their charges but reaped a golden harvest.

PRESIDENT F. NICHOLLS gave an evidence of his thoughtful courtesy in presenting every lady at dinner Wednesday evening with a bouquet of roses.

SOUVENIRS were more in evidence at this convention than ever before, and included samples of wire and cable mounted as letter weights, X-ray coin purses, mirrors, cigars, real and wooden, match safes and holders, lead pencils, metal pencils, pocketbooks, badges, planigraphs, cases for wiring rules, memorandum pads, cigar cases and a great many other objects of bigotry and virtue. The intrinsic value of many of these presents was considerable, but, in spite of the demand, the supply held out surprisingly.

THE CAKE WALK.—On Tuesday night, Messrs. Dale and Carroll entertained the members and the ladies with a cake walk in the most approved Afro-American style. The exhibition evoked roars of laughter and the cake was voted to the walkers by unanimous consent. The walk took place very appropriately in the ball room, which was crowded with enthusiastic onlookers.

MR. C. O. BAKER, Jr., was very successful again in his work as Master of Transportation, although the spell of summer holiday beginning at noon on Saturday interfered with the success of the special trains. Still, as there were delegates and visitors from twenty-five States, Canada and England, Mr. Baker must have felt that his share in bringing the convention together was not without its happy results.

MR. C. R. HUNTLEY, of the Buffalo General Electric Company, more than sustained his reputation as a charming host by the breakfast he gave at Lewiston, at the foot of the Gorge, on Wednesday morning, to a party of twenty-five friends. A special car was provided, which ran over the Gorge road, and whose trip over that wild and romantic railway, along the edge of the rapids, through the morning mists —and with the aid of a Whirlpool cocktail—will not be soon forgotten. The party included Messrs. Huntley, Nicholls, Insull, Gilbert, Hamill, Baker, Porter, Dana Greene, Seely, Habirshaw, Ferguson, Rhotehamel, Martin, Brackenridge, Ridall, McIntire, Requa, Brophy, Henderson, Flood, Brooks and others. A delicious fish breakfast was served, the chief items of which had been drawn from the cold storage of the placid river but a few minutes before, and many of the guests were tempted to believe they could live on fish forever. Only President Nicholls and Secretary Porter appeared to care whether any convention was held that day. The reason for calling the road the Gorge Route was understood by the time the meal was finished, and as one of the party said, they were all about as slow as Niagara in eating their way backward to the Falls. On the trip home, Mr. Huntley had a photograph taken of the party at the Buttery Rapids, as a souvenir of the occasion.

---

[1] See page 676.

Mr. BANKER R. PAINE, of Drummondville, Ont., was able to show a good many inquirers the nature of the ground around Chippewa and Navy Island, where it is now seriously proposed to undertake a large development for power by a canal coming out on the bluff just above Cedar Island.

SHAWMUT FUSE WIRE COMPANY, of Federal street, Boston, Mass., displayed a line of new switches, notably their quick break switch, which was recently passed on very favorably by the Boston Fire Underwriters. The exhibit was in charge of Mr. H. P. Moore.

THE JANDUS ELECTRIC COMPANY, Cleveland, O., exhibited on the ground floor nine different patterns of their enclosed arc lamps comprising constant potential, constant current, alternating, railway power current; a direct burning 220-volt lamp, short type, etc. The exhibit was a very interesting one, and was in charge by Mr. Geo. R. Lean.

THE DIAMOND ELECTRIC COMPANY, located on the ground floor of the hotel, exhibited the Scheeffer transformer and wattmeter, which is claimed to be a marked improvement on the old style, this new transformer being the core type instead of the shell type. Their wattmeter also was shown and attracted attention by its simplicity of construction. They exhibited also the Cardew earthing device, which they manufacture under English patents. It is used for the purpose of protection of buildings and life against high pressure currents. The exhibit was in charge of Mr. G. A. Scheeffer and Mr. Wm. Wilson.

BUCKEYE ELECTRIC COMPANY, Cleveland Ohio, exhibited a very attractive case of their incandescent lamps of every variety and in different colors. The exhibit showed their latest designs of ornamental and decorative lamps. Also candelabra lamps for high voltages, covering a new field. Mr. John R. Massey, the factory superintendent of this company, had charge of the exhibit.

CUTTER ELECTRICAL MANUFACTURING COMPANY, Philadelphia, Pa., showed their full line of I-T-E circuit breakers. The I-T-E motor starting rheostat, their latest device, created unusual interest. It is a new device affording a very high standard of protection. The exhibit was in charge of Mr. Henry B. Cutter, president and general manager of this company.

MR. T. H. BRADY, of New Britain, Conn., showed samples of his cut-out box, which is having a large demand among the trade the past year. Mr. Brady is one of the original members of the National Electric Light Association and has an unusually large acquaintance, forcibly illustrated by his continual handshaking with friends met at the convention.

PERU ELECTRIC MANUFACTURING COMPANY, Peru, Ind., had a large board tastefully arranged, showing a varied line of their china insulation, also their well known Hercules and Laclede batteries. Among their specialties we noted cut-outs, transformer fuse boxes, conduits, tees, ells, crosses, etc., also new multiple tablet boards for two and three-wire systems. The exhibit was in charge of Mr. D. A. Schutt and F. D. Covington.

CLOOS BOX. Adjoining the exhibit of the Diamond Electric Company was the Cloos high potential junction box for alternating and direct current. The main feature is that it allows the testing out without cutting any joints or cables. It is extremely simple in construction. The device is meeting with favor from many concerns interested in underground construction. H. M. Underwood & Company, Chicago, Ill., are the general agents for this junction box.

L. A. CHASE & COMPANY, 161 Fort Hill Square, Boston, showed on the ground floor a full line of their new junction boxes and couplings, which attracted considerable attention due to the novel method of connecting conduits. They exhibited also the well known "Elden" alternating circuit breaker, which is now being extensively used by the largest companies throughout the country. They reported a number of good sales made at the convention. The exhibit was in charge of the general manager, Sears B. Condit, Jr.

PARTRICK & CARTER COMPANY, Philadelphia, Pa., exhibited on the ground floor a large line of push buttons, bells, annunciators and other electrical specialties, all of which were of interest to central station men, upon whom the diversity of the demand becomes daily wider and more surprising.

STANDARD UNDERGROUND CABLE COMPANY, of Pittsburg, Pa., had an extensive and complete exhibit of their superior line of cables in Parlor G on the first floor of the International Hotel. Their line comprised notably lead-covered cables for underground installation for electric lighting, their celebrated "Tip Top" brand and "Sterling Brand" rubber covered wire, etc. The exhibit was well arranged and in charge of Geo. L. Wiley and Mr. Thomas Hughes.

HOPE ELECTRIC APPLIANCE COMPANY, Providence, R. I., had an excellent exhibit of their latest designs of switches for direct and alternating current; also lamp hanger boards, mast arms, tree insulators and pole steps. They distributed catalogues and circulars of their specialties, and reported also having made a number of sales on the premises. The exhibit was in charge of Messrs. Robt. Fessenden and John I. Drake.

C. C. GARTLAND, 370 Maryland street, Buffalo, displayed his recent invention, a regulator for arc dynamos, the object of which is to regulate the current so that at 1-10 ampere increase or decrease the regulator will come into action and bring the current to normal strength again. The regulator created quite an impression on all visitors for its high value and simplicity. The inventor himself, Mr. C. C. Gartland, had charge of the exhibit and will be pleased to send descriptive circulars to all inquirers regarding the device.

H. B. CAMP COMPANY, Aultman, Ohio, displayed sections of their underground and interior conduits of vitrified clay and metal covered clay; also junction boxes. A neat catalogue was also distributed by their Mr. A. L. Daniels, who had charge of the exhibit.

WELLS, FARGO & COMPANY'S EXPRESS, through their agent at the hotel, Mr. W. C. Clark, distributed a highly interesting souvenir in the shape of a neat box containing pure carborundum crystals, composed of coke, sand, salt and sawdust as taken direct from the electric furnace.

BELKNAP MOTOR COMPANY, Portland, Me., had an exhibit which attracted considerable attention from many visitors at the exposition. Their ingenious device, "The Chapman" direct and alternating current voltage regulator was shown in active operation in conjunction with their small alternating current generator and exciter. A number of instruments were sold on the premises, which certainly speaks well for the device. This was also partly due to the curves displayed of actual results recorded on a chart taken from a self-recording voltmeter in a station having the regulators in use. The exhibit was in charge of the Brewster Engineering Company, of Thames street, New York, selling agents. The operation of the instruments was shown by Mr. W. H. Chapman, of Portland, Me.

H. W. JOHNS MANUFACTURING COMPANY, New York, showed a very interesting exhibit of some of their electrical specialties, among which were a new arc lamp hanger and the "Toggle clamp" insulator. Their electrotherm heating pad and H. W. J. street car heaters were shown in operation on the hotel circuits. The simplicity of operating and the method of regulating the temperature by a simple switch interested a large number of persons. Samples and descriptive circulars were freely distributed. The exhibit was in charge of Mr. W. F. D. Crane.

THE BRYANT ELECTRIC COMPANY was well represented at the convention by Mr. L. W. Eaton, Mr. W. C. Bryant, Mr. J. B. Hubbell, Mr. E. M. Scribner, of the Eastern office, and Mr. E. R. Grier, of the Chicago office.

K. McLENNAN & COMPANY, of Chicago, manufacturers of the celebrated Gale's commutator compound, displayed on the ground floor of the hotel a full line of their compound samples, which were eagerly sought for by the delegates. The exhibit was in charge of Mr. J. Isaacs, who reported having also made satisfactory sales of the Gale's commutator compound. Souvenir leather memorandum books, with the firm's advertisement, were widely distributed.

ELECTRIC ARC LIGHT COMPANY, of New York, manufacturers of the Pioneer enclosed arc lamp, exhibited a number of their 150 hour arc lamps of different designs adapted for both indoor and outdoor purposes. The high efficiency, steadiness and pure white light this lamp produced attracted unusual attention and drew a large number of visitors to their headquarters, situated on the main floor of the hotel.

They reported also having booked a number of nice orders. The exhibit was in charge of their genial general manager, Mr. Harry Astruck. Many visitors were also entertained at the exhibit by the inventor of the Pioneer enclosed arc lamp, Mr. L. B. Marks. Their souvenir, a sterling silver match box, was unquestionably one of the handsomest things of its kind ever given away at an electric convention, the supply very shortly not equaling the demand. Literature in regard to the enclosed arc lighting art was also freely distributed.

HUGO REISINGER has done splendid work in educating the electrical public up to the use of better carbons and he received plenty of evidence at the convention that his efforts had been appreciated. The "Electra" carbons have become widely popular through his persistent and intelligent work.

MR. W. D. PACKARD, of the New York and Ohio Company, Warren, Ohio, was there to speak for the celebrated incandescent lamps bearing his name.

PETTINGELL-ANDREWS COMPANY, of Boston, were represented by their Mr. C. B. Price.

BRUSH ELECTRIC COMPANY had Mr. W. S. Rogers on from Cleveland, where "the Colonel" still hangs on gallantly.

PHOENIX GLASS COMPANY, New York, had again entrusted their cause to Mr. E. H. Peck, and in the hands of that young veteran of conventions it seemed quite safe.

CENTRAL ELECTRIC COMPANY, so long and widely known among central stations, could not have sent a better representative than Mr. George A. McKinlock, who made no exhibit but found himself extremely busy meeting central station and other friends. He reports a very large trade and a hopeful outlook.

MR. J. T. McROY, of Chicago, came on from New York to speak a piece or two in favor of his conduit, which has lately been contracted for by several large new plants, and is rapidly becoming very well known.

MR. J. P. McQUAIDE, the buoyant, blithe and debonnaire, graced the occasion as usual in behalf of the National Conduit and Cable Company. His company is busy up to the hilt, and he proposed to keep the blade fleshed.

PARANITE INSULATED WIRE COMPANY, Jonesboro, Ind., were in line with Mr. R. E. Lucas, to present armfulls of samples for them.

MR. F. M. LAUGHLIN came to speak for the Solar Carbon and Manufacturing Company.

ELECTRIC APPLIANCE COMPANY, of Chicago, who have built up so large a supply trade among stations, distributed their neat little house paper and sent Mr. W. W. Low, without whom no such gathering is now complete.

ELECTRIC STORAGE BATTERY COMPANY, of Philadelphia, were represented direct from headquarters by Mr. Herbert Lloyd himself. Quite a change has come over the central station companies to-day, and their demand for batteries, once nil, is now simply enormous. Mr. Lloyd did not have a single spare moment.

PERKINS ELECTRIC MANUFACTURING COMPANY were present in the person of Mr. C. I. Hills, who did not have to add much to his circle of acquaintances, large as the convention was.

MR. E. O. JOHNSON was the embassy from the Boston Electric Company, the Boston supply house.

MR. R. S. HALE, of Boston, was present as the American agent of the Wright meter, the discussion of which was so marked a feature of the convention proceedings.

HEINE SAFETY BOILER COMPANY, knowing that water is sometimes turned into steam for running electrical plants, wisely sent a persuasive talker in the person of Mr. C. D. Humphrey, who hasn't much use for turbines while he can recommend such a good boiler.

THE ERIE CANAL was represented by Mr. John A. Seely.

CHARLES A. SCHIEREN & CO.'S leather belting found an active advocate in Mr. A. N. Harvey.

OKONITE COMPANY were represented by Capt. W. L. Candee and G. S. Manson. They made no special exhibit, but gave away a clever little souvenir in the shape of a key pencil, the handle of which formed in the shape of the famous Okonite trade-mark. But these gentlemen needed no key to open their way to the hearts of the delegates.

AMERICAN ELECTRIC COMPANY, of Detroit, was represented by W. J. Hastings.

NEW YORK INSULATED WIRE COMPANY had present Messrs. Hoover and Woolf, both of whom had a host of friends to renew touch with and give quotations to.

THE STERLING COMPANY, of Pittsburg, were represented by Mr. W. Elliott.

CORNMAN COMPANY, of Cleveland, Ohio, were represented by Mr. R. C. Foster.

INTERIOR CONDUIT AND INSULATION COMPANY were quietly but none the less ably represented by Mr. D. C. Durland, of the engineering staff, who reported that the factory is running with fullest activity in all its lines of conduit, fan motors, power motors, generators, switch specialties, etc. Mr. Durland has plans in hand for several new installations.

MR. A. L. DANIELS, on behalf of the H. B. Camp Company, of Aultman, Ohio, not only made a neat exhibit of their terra cotta conduits, but gave away pocket match safes that were in great demand. He accompanied several delegates to the great power house to show them the Camp conduit there.

WASHINGTON CARBON COMPANY was vouched for by Messrs. L. M. Baine and J. S. Creder.

PUTNAM ELECTRIC COMPANY, of Boston, had their Mr. M. H. Baier on the ground.

AKERMAN ELECTRIC WORKS, of New York, sent Mr. J. R. Belote as their official mouthpiece.

CUTTER ELECTRIC COMPANY, of Philadelphia, could have desired no better spokesman than its chief, Mr. H. B. Cutter, whose opinions and influence carry weight with all who have the pleasure to know him.

ARMORITE CONDUIT interests were very ably looked after by Mr. J. F. Cummings, who had a practical illustration of their work to show in the high tension conduit that has been working successfully for two years on the main street of Niagara Falls. It was visited and admired by many delegates.

MR. R. B. COREY, in behalf of the Simplex wires and Columbia incandescent lamps, and General Incandescent arcs, demanded and received a most respectful consideration.

HABIRSHAW WIRES AND CABLES were very much to the fore, having present Dr. W. M. Habirshaw, J. W. Godfrey and Frank Harrington. The pretty Habirshaw celluloid badges flying the Stars and Stripes were seen by the thousand all over the town, and the greatest desire to get them possessed not only the delegates, but all the pretty girls both sides of the river. The Habirshaw cables and bus-bars at the big power house were the subject of the greatest interest, and elicited many high encomiums.

FORT WAYNE ELECTRIC COMPANY were represented by Messrs. C. S. Knight, J. J. Wood and J. Adott.

MR. C. T. BURNS was in his own person an adequate representative of the Burns supply interests of Rochester, N. Y.

FARADAY CARBON COMPANY were represented by Mr. A. E. Carrier.

BEACON LAMP COMPANY were represented by E. H. Allen.

PHILLIPS INSULATED WIRE COMPANY were represented by Mr. H. C. Adams, secretary, who had some samples of their product.

BAKER & CO., platinum merchants, were represented by Mr. C. O. Baker, Jr., of the firm.

WYKOFF CREOSOTED WOOD CONDUIT COMPANY were represented by H. L. Allen.

NATIONAL TUBE WORKS, of McKeesport, Pa., were represented by their general sales agent, Mr. F. R. Upton.

MR. McLEOD, manufacturer of desk lights, spark arresters, etc., did not find much spare time at the convention, there were so many people who wanted to see him about his goods. Mr. McLeod represented McLeod, Ward & Co., New York.

THE CANADIAN GENERAL ELECTRIC COMPANY were represented by Messrs. Frederic Nicholls and F. C. Armstrong.

MR. KIELY, of Kiely & Mueller, New York, was present in the interests of their steam specialties, and gave an excellent exhibition of their well known devices for greater economy and safety in the use of steam and water.

MR. S. M. HAMILL, general manager of the Brush Company, found many friends among the delegates and received numerous compliments on the new Brush multiple circuit arc machines. We may soon expect to hear of further developments in the Brush machine.

ELMER P. MORRIS, of New York, displayed a large number of the specialties for which he is the agent, in Rooms E and F, Cataract House. His popularity is always in evidence and was shown by the large number of friends and customers visiting his rooms. Among his specialties we noted the Keystone volt-ammeter, Nowotny long burning arc lamp, Garton-Daniels lightning arrester, Electric Railway Equipment Company's iron poles and brackets, etc.

GALE'S COMMUTATOR compound was used for three consecutive days on the generators in the Westinghouse Company's exhibit at the convention. Sample sticks were in great demand among the delegates and visitors.

AMONG THE VISITORS we noticed Mr. W. H. Lawrence, president of the National Carbon Company, Cleveland, Ohio.

THE ROCKWOOD MANUFACTURING COMPANY, of Indianapolis, Ind., exhibited on the ground floor of the International, a small dynamometer which illustrated in an admirable manner the greatly superior adhesive power of that company's paper pulleys, as compared with the ordinary iron pulley. A section of one of their pulleys, which had been run for many months, showed practically no wear at all. The dynamometer demonstration spoke so eloquently that Mr. G. O. Rockwood, in charge of the exhibit, had very little left to say. We understand that he takes home with him a good list of orders as a result of his visit.

WAGNER ELECTRIC MANUFACTURING COMPANY, of St. Louis, Mo., exhibited a self-starting, single-phase, alternating current motor on the main floor of the International. Their alternating current switchboard instruments were well displayed at Parlor C and D, at the Cataract House; also their ceiling fans and a multipolar direct-current motor. Both displays attracted a large number of visitors, and, we are informed, quite some business resulted from their exhibit. We noted the presence at the exhibit of Mr. Herbert A. Wagner, Mr. Fred Schwetman, Mr. John Mustard and Mr. H. H. Mustard.

INTERNATIONAL ARC LAMP COMPANY, Houston and Mercer streets, New York, distributed one of the handsomest catalogues at the convention. Fine half tones illustrate their lamps, and the many uses they can be put to, both for interior and for outside illumination. The catalogue is worth while writing for. This method of lighting shows a most decided advance. The genial Mr. McIntire, the inventor of this lamp, represented the company at the convention.

DIEHL MANUFACTURING COMPANY, Elizabethport, N. J., were represented by Mr. B. C. Kenyon and Mr. Edwin H. Bennett, Jr., who both were kept busy receiving their many friends. The Diehl Company's electric fan catalogue was also distributed at the convention, and showed excellent cuts, etc., of their column, electrolier ceiling fans, and others in different styles and designs.

THE BOSSERT ELECTRIC CONSTRUCTION COMPANY, Utica, N. Y., exhibited on the main floor their specialties, among which we noted their 500 ampere circuit breaker and switch, also a line of panel boards and branch boxes. They distributed circulars of their specialties. The exhibit was in charge of Mr. W. F. Bossert.

ADAMS-BAGNALL ELECTRIC COMPANY, Cleveland, O., showed series open and enclosed arc lamps both for street and interior illumination; open, alternating and enclosed constant potential arc lamps, also. Excepting ship projectors or search lights, this firm manufactures every form of arc lamps. The exhibit was in charge of Mr. Thos. E. Adams.

AMERICAN ELECTRIC HEATING CORPORATION, Boston, exhibited their many heating devices for varied purposes and distributed interesting circulars on main floor of hotel. It was perhaps due to the wonderfully cold weather that so many delegates evinced a yearning interest in heating devices tapped on light circuits. There is nothing to equal a little practical demonstration of the ease and feasibility of new apparatus of this character. Mr. J. I. Ayer attended for the Corporation.

WESTERN ELECTRIC COMPANY, Chicago and New York, displayed their latest model fans, etc., and distributed sample cards of their W. E. weather-proof wire. Many other pamphlets and circulars relative to electric light and power apparatus were given out by the company.

MR. F. S. TERRY was present to advocate with wonted directness and perspicacity the interests of the Sunbeam lamp.

J. P. WILLIAMS, of Cortlandt street, New York, general agent for the Paragon fan, exhibited on the ground floor of the hotel a large number of his latest types of fans artistically arranged in the form of a pyramid consisting of 50 motors all styles, sizes, and colors; also several very handsome ones entirely nickel plated. They were all connected and in operation at the same time. The novel effect produced was immediately proved by the large number of visitors attracted one result of same being that the exhibit in itself was quickly sold for delivery after the convention. The exhibit was in charge of Mr. J. P. Williams personally. Descriptive catalogues and a unique advertising card were distributed.

AUTOMATIC CIRCUIT BREAKER COMPANY, Newaygo, Mich., exhibited on the ground floor their non-arcing automatic circuit breakers, which interested a large number of visitors at the convention.

D. & W. FUSE COMPANY, Providence, R. I., displayed on the ground floor of the hotel different sizes and kinds of non-arcing fuses of different voltages, in charge of Messrs. Fessenden, Drake and Woodward. The device was very fully described in the last issue of The Engineer by Wm. Woodward under his own signature.

MITCHELL TEMPERED COPPER COMPANY, Corry, Pa., displayed their commutator bars, and bus-bar clamps on ground floor. The exhibit was in charge of Mr. G. Ruhl.

MR. M. R. RODRIGUES, 19 Whipple street, Brooklyn, N. Y., showed a sample line of motors, the only distinctive exhibit of battery motors at the convention. They were located in parlor 9 of the International Hotel in connection with the exhibit of J. P. Williams, Paragon fan motors.

GENERAL ELECTRIC COMPANY. The exhibit of the General Electric Company was small, but dealt with such apparatus as most nearly concerns managers of lighting stations. Briefly the exhibits covered arc lighting, meters, transformers, lightning arresters, and general appliances. The principal exhibit was a handsome board equipped with a type of every metering and measuring device manufactured by the company. On the board were mounted recording wattmeters of every kind, the principal being a large capacity meter for measuring total station output of 2,500 amperes and over. The meter specially built for the three-wire service of the Edison Electric Illuminating Companies, was shown beside the power meter for motor service on 500-volt circuits, and the new street car meters designed for attachment to street cars, to measure the consumption of current by the car, and to act as a check on the motorman. Considerable attention was attracted by the new Prepayment meter presently to be placed upon the market. In combination with the meter is a coin-receiving device by means of which a consumer is enabled to pay for his light beforehand, know how much he has paid, and receive only what he has paid for. The operation of this instrument was very carefully explained to the delegates by Mr. Caryl D. Haskins. A Thomson astatic ammeter and an astatic voltmeter were also exhibited, the voltmeter being placed on the circuit of the Gorge railway. It was absolutely deadbeat, the needle being held to its indication without a tremor. The instrument exhibit was completed by a full line of the Thomson inclined coil instruments for both switchboard and portable use. The arc lighting department was represented by samples of the single solenoid lamp, the long burning lamp for 220-volt circuits, the focusing lamp for series arc circuits, the enclosed long burning lamp for 110-volt circuits, and that for alternating current circuits. Several lamps were hung under the hotel arcade, and every opportunity was afforded of examining them in operation. In order to enable delegates the better to comprehend the structure of the lamps, all the different parts were shown unmounted. Samples of the direct current lightning arresters for circuits up to 850 volts, formed part of the exhibit, as well as the Wirt short gap lightning arresters, a description of which recently appeared in these columns. The type H transformer, the most recent type developed by the General Electric Company, also occupied a prominent position in the room. The method of building up this transformer was shown by parts in different stages of construction, and its performance by a series of charts giving the efficiency, core loss and regulation curves. A testing transformer for measuring insulation was also shown and explained. It is offered as a substitute for the old methods, and is designed for measuring such insulation as is necessary with the higher voltage currents of to-day. An X-ray set completed the exhibit of the General Electric Company. This was shown during the afternoons and evenings, and while in operation attracted large crowds to the rooms. On Tuesday all the foreign delegates to the Postal Congress, under the guidance of Gen. Batchelor, witnessed a special exhibition given for their benefit by Mr. F. M. Kimball and Mr. Haskins. The company distributed a tasteful souvenir book, illustrative of Niagara Falls and the work which it has done in connection with the utilization of their power. It also presented the delegates with a "planigraph" or wire calculator. This was highly appreciated. For the ladies the company prepared a handsome little silver mounted souvenir. The parlors of the company were decorated with framed diplomas, and with some excellent enlarged photographs of its important installations and apparatus. Its representation included the following gentlemen: Prof. Elihu Thomson, Schenectady, N. Y., S. Dana Greene, W. L. R. Emmet, J. R. Lovejoy, H. C. Wirt, J. M. Andrews, J. W. Kirkland, G. DeB. Greene, J. H. L. Hilman, C. P. Steinmetz. Harrison, N. J., M. K. Eyre, A. D'A. Sage. Boston, Mass., Chas. W. Davis, A. R. Bush, F. M. Kimball, Caryl D. Haskins, S. B.

Paine. Lynn, Mass., W. D. Ryan. New York, C. E. Estabrook, J. McGhie. Philadelphia, H. J. Buddy, D. R. Bullen. Pittsburg, Pa., J. C. Calisch. Cincinnati, O., L. H. Cooper, E. K. Gillette. Syracuse, N. Y., H. H. Crowell. Columbus, O., T. W. Dixon. Baltimore, Md., J. P. Judge. San Francisco, W. M. Ray.

WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY.—The display made by the Westinghouse Electric and Manufacturing Company attracted great attention. Several lines of important apparatus were in view and in actual operation. Among them was a 15 horse-power, 500-volt D. C. motor, driving a 7½ horse-power, 125 volts D. C. generator, and a 10 horse-power, 100 volts A. C. D. C. two-phase generator. From the A. C. circuits were operated a 1 horse-power two-phase induction motor, constant potential arc lamps, induction motors, etc. The circuits were all supplied with the Shallenberger wattmeters, showing their operation to great advantage. A full line of converters were exhibited from the smallest size up to a 25 k. w. converter in oil. The new type of panel switchboards was on exhibition for both A. C. and D. C. generators. A full line of lightning arresters was shown both for arc and incandescent high potential circuits.

The exhibitions of the Westinghouse Electrical Manufacturing Company and the Sawyer-Man Electric Company were situated in the south end corner upon the veranda of the International Hotel, where a large parlor and a private office had been engaged. The parlor was very tastefully decorated, and in front of the windows, as well as in the interior, numbers of incandescent lamps, three constant potential arc lamps illuminated the exhibits at night. A large amount of literature descriptive of the Westinghouse Company was also on hand for distribution among the delegates and guests. Good-sized photographs of the apparatus which the Westinghouse Company installed at the plant of the Niagara Falls Power Company were suspended from the wall, and attracted a great deal of attention. The exhibits were in charge of Mr. W. K. Dunlap and Mr. M. McLaren, of Pittsburg, Pa. The Westinghouse Company were represented at the convention by the following gentlemen: C. F. Scott, B. G. Lamme, C. A. Bragg, T. B. F. Paine, F. S. Smith, Maurice Coster, Paul T. Brady, T. C. Frenyear, F. N. Waterman, W. K. Archbold, H. P. Davis, Clarence A. Ross, E. H. Heinrichs, R. S. Feicht, Arthur Hartwell, C. S. Skinner, C. F. Medbury.

THE SAWYER-MAN LAMP COMPANY, of Allegheny, Pa., had a very attractive exhibit in connection with the Westinghouse display, consisting of lamps of various candle-power and voltage. The principal feature of this exhibit was the display of 220-volt lamps. The very long filament necessary for a thoroughly satisfactory lamp of this high voltage is rendered perfectly stable by means of the three-point support for the loop, making impossible the short circuiting of the carbon due to vibration or jarring. The lamp was illustrated in the last issue of The Electrical Engineer. Attention was also called to the glass bridge between the leading-in wires which serves as a support for the anchor, from the stem. It is a well known fact that a 220-volt lamp, if made after the standard type, is liable to short circuit across the leading-in wires, this device rendering impossible such short circuiting.

CALIFORNIA ASPHALT COMPANY, whose Alcatraz paints are now being pushed with such vim and success, was represented by Mr. A. B. Clerment.

MR. B. E. GREENE was there gaily paddling his own canoe and some other fellow's whose name he forgot to mention.

THE THRESHER ELECTRIC COMPANY, of Dayton, O., were represented by Mr. H. A. Thresher.

THE EDDY ELECTRIC COMPANY found a devoted and successful pleader in Mr. A. D. Newton, who could instance offhand, at any moment, scores of their successful power and lighting plants in any part of the country. The popularity of the Eddy apparatus is nothing short of phenomenal, and Mr. Newton has seen and contributed to its every advance from the beginning.

MR. B. G. UNDERWOOD was the alert and able correspondent of the Boston "Herald" and the "Transcript," to both of which he sent copious reports of the proceedings, setting a good example to the New York dailies, whose chief aim in life is to write up some new sensation in crime.

BRYAN-MARSH COMPANY and the Imperial lamp were represented by Mr. J. I. Solomon, who had some curves to show consumers that were as interesting as those of Amos Rusie and just as effective.

CROUSE-TREMAINE CARBON COMPANY, Fostoria, O., were represented by principals, well known to the trade and found many users of their product at the convention.

SAFETY INSULATED WIRE COMPANY were represented by Mr. Requa, who could point with pride to the large amount of his product used in connection with work at the Falls.

AMERICAN ELECTRICAL WORKS, Providence, R. I., through Mr. Ackerman, made a distribution of handsome letter weights formed from samples of their copper cable used for the Niagara power transmissions. These mementoes were in brisk demand.

MR. S. M. HAMILL, JR., vice-president and general manager of the Brush Electric Company, was one of the best known of the manufacturers on the ground, and he had the great advantage of being able to point to standard Brush apparatus in use in every direction at or around Niagara. Brush arc lighting machinery was early popular at the Falls and the whole region has for years basked at night in the steady beams of the Brush arc lamps. A great deal of the old apparatus, now running for years, still remains in service, but Mr. Hamill has had the pleasure of selling more, from time to time, as, for example, at Buffalo, where he has sold Mr. Huntley a large number of the 65 lighters and the big new 125-lighters, no fewer than eleven of these being now in use. The new Niagara lighting plant also includes four 100-Brush arc lighters, and Mr. Hamill was able to use these as forcible arguments with managers still hesitating about big arc dynamos.

THE WALKER COMPANY, of Cleveland, Ohio, were represented by Messrs. H. McL. Harding, J. Holt Gates, Abbott, William Gibbs, H. D. Gay. Protoghaphs were shown of large sized machines with details of same, particularly of some of their 1,500 kilowatt generators now in operation in Kansas City. Much interest was manifested in their new alternating machinery, many visitors calling to investigate the subject. It is the intention of the Walker company to immediately bring out a complete line of slow speed induction alternating dynamos. The Walker company's new departure in competing for the arc light business of the country with their new multiple circuit large size arc dynamos was largely commented on by the delegates. The Walker company received many congratulations on the completeness of their line of circulars, giving most complete details of the apparatus manufactured by them.

CUTTER ELECTRIC AND MANUFACTURING COMPANY were represented by Henry B. Cutter and H. B. Kirkland, who had an exhibit of their new starting box and circuit breakers.

THE AMERICAN CIRCULAR LOOM COMPANY were represented by H. B. Kirtland and H. H. Brooks, general managers, who had on exhibit samples of their products and their new flexible armored tube. Mr. K. reports business very good.

JEWELL BELTING COMPANY was represented by Mr. C. L. Tolles, who firmly believes that belting men will long find it worth while to attend electrical conventions. It is true a few large plants get along without belts, but the vast majority, he says, still need them and use them.

HART & HEGEMAN MANUFACTURING COMPANY, Hartford, Conn., were represented by Mr. A. L. Pease, who found no trouble in securing a favorable audience at any moment for his monologues on the Hart switche specialties.

STANDARD THERMOMETER & ELECTRIC COMPANY, Peabody, Mass., makers of the well known Upton arc lamps, were represented by Mr. W. L. Livingston.

STANDARD PAINT COMPANY and all its famous P. & B. specialties were in the watchful care of Mr. H. W. Benedict.

J. A. ROEBLING SONS CO. were represented by Mr. W. J. Barrett.

MR. H. H. BROOKS did not indulge in circumlocution in talking about the product of the American Circular Loom Company, of Boston. He had a long list of places in which it has been installed.

PASS & SEYMOUR, the well-known makers of porcelain insulators, were represented by both the titular members of the firm, who found plenty of users of their insulators present.

J. G. WHITE COMPANY were represented by Mr. White himself, who read one of the best papers at the meeting.

AM. DIST. STEAM COMPANY, of Lockport, N. Y., were represented by Mr. Babcock, whose advocacy of the Holly system for using exhaust steam has converted more than one station to this method of enforcing economy and making larger profits.

MORE NIAGARA POWER WORK.

The Niagara Falls Power Company have awarded the contracts for the extension of the power house and wheel pit. The New Jersey Steel and Iron Company will furnish and erect the structural steel; R. D. Young, of Niagara Falls will do the mason work; Brass Brothers, of Niagara Falls, will do the carpenter work; the Westinghouse Electric & Manufacturing Company will build the new 5,000 horse-power generators, and the I. P. Morris Company, of Philadelphia, will build the turbines. The work is all expected to be completed by fall, so that the new installation may be then operated.

SOCIETY & CLUB NOTES

SEVENTH ANNUAL MEETING OF THE CANADIAN ELECTRICAL ASSOCIATION.

THE seventh annual convention of the association was held on the 2d, 3d and 4th of June in the Convention hall of the Dufferin Café, Niagara Falls, Ont., and proved to be one of the most largely attended and interesting in the history of the association, there being a noticeable increase in the number of central station men present.

A large number of new members were enrolled.

The following is a list of those present: Barrie, F. Peplar; Brockville, Henry Comstock; Buffalo, C. H. Philbrook, H. E. Adams; Chatham, James Lamont; Carleton Place, G. Brown; Fort Wayne, Ind., Thos. Duncan; Halifax, N. S., E. F. Freeman; Hamilton, Geo. Black, W. F. McLaren, F. W. Martin; Ingersoll, Stephen Noxon, G. E. Gayfer; London, C. B. Hunt, C. E. A. Carr; Lindsay, B. F. Reesor; Montreal, W. H. Browne, John Carroll, Wm. Thompson, J. A. Bayliss; Niagara Falls, G. Phemister, Wilfred Phillips, G. E. Foster; New Glasgow, F. A. Bowman; New York, W. J. Johnston; Ottawa, J. Murphy; Peterboro, H. O. Fisk; Port Hope, V. B. Coleman; Sarnia, G. Shand, W. Williams; St. Catharines, E. E. Cary, G. A. Pewell; St. Thomas, J. Farley; Seaforth, W. H. Bullard; Toronto, K. J. Dunstan, Frederic Nicholls, J. J. Wright, Geo. A. Wilkie, E. K. M. Wedd, Irving H. Smith, C. H. Mortimer; A. A. Christie, A. B. Smith, J. A. Kammerer, W. A. Johnson, A. M. Wickens, W. J. Clarke, E. D. McCormick, W. H. Bourne, Albert Esling, T. F. Dryden, James Milne, F. H. Leonard, Jr., J. W. Campbell, Jos. Wright, E. B. Biggar, John C. Gardner, Ross McKenzie; Guelph, J. Yule; Sault Ste Marie, J. A. Taylor; Walkerville, J. W. Purcell; Welland, C. G. Page; Toronto, G. Angus, official reporter.

The President, Mr. John Yule, of Guelph, opened the convention by delivering a very interesting address; he stated that the agitation in favor of municipal ownership was growing in favor and some scheme would have to be devised to protect the electric lighting business; it should be shown to the Government that it was for them to provide for the compulsory transfer and purchase of properties in cases where the local authorities assumed control of the lighting service, and thus prevent invested money being wasted. He referred in fitting words to the untimely death of the second vice-president, Mr. E. Carl Breithaupt, of Berlin, who had been killed by an explosion.

The minutes of the last convention were read by the secretary-treasurer, Mr. C. H. Mortimer, and adopted. The secretary-treasurer's report showed an increase during the year of 42 active and 2 associate members; 9 active and 5 associate members had resigned, and 6 active members withdrawn, owing to removal. There were 33 active and 14 associate members struck off the roll for non-payment of dues, and death had removed Messrs. Breithaupt and Congdon, the membership now standing at 154 active, and 19 associate members.

MR. C. B. HUNT referred to a recent Order in Council issued in regard to the inspection of meters. He stated that the charge for inspection of meters was now to be made per lamp, instead of per ampere, which meant a considerable increase to those who had a 106 or 110-volt service. He thought some action should be taken in the matter.

MR. JOHN MURPHY read a very interesting paper on "Water Driven Plants," which was well received and upon which there was considerable discussion.

MR. WICKENS then read his paper entitled, "The Steam End of an Electric Plant," upon which many practical points were brought out in the discussion.

At the invitation of the Buffalo and Niagara Falls Electric Railway Company, the convention enjoyed a trip over their road to Buffalo, and there inspected the Buffalo power house, where the members of the association were given an opportunity of seeing what could be done in long distance transmission of electric power.

SECOND DAY.—The convention was resumed at 10 a. m. The following committees were appointed:

On Statistics: Messrs. A. B. Smith, A. M. Wickens, O. Higman. Meter Inspection: Messrs. J. J. Wright, Berkeley Powell, James Milne. Legislation: Messrs. John Yule, B. F. Reesor, J. J. Wright, J. Farley, W. H. Comstock, C. B. Hunt, S. J. Parker and F. Peplar.

MR. J. A. KAMMERER read a paper on "Day Loads for Central Stations and How to Increase Them." Mr. J. J. Wright was dubious about the economy of operating incandescent lighting and power from the same machine.

MR. BROWNE named three things which must be taken into account, namely, capital invested, cost of labor, and supply cost, such as coal and oil, etc. This paper brought out considerable discussion.

MR. WM. THOMPSON presented a paper entitled, "Determination of the Heating Power and Steam-Producing Value of Coals from a Preliminary Examination."

MR. MILNE suggested that Mr. Thompson's method of determination was not altogether to be relied upon as there was a great difference in coal and the only way to overcome the difficulty would be to compel the mining companies to furnish the same grade of coal at all times.

After the adjournment for dinner a visit was paid to the Niagara Falls Park and River Railway power house.

Considerable discussion was evoked over the choice of a place to hold the next convention. Mr. Browne, of Montreal, very vividly pictured the benefits to be derived from a visit to that city, and the association decided to hold the next convention there, the time of holding the same to be left in the hands of the Executive.

In the afternoon the following officers were elected: Mr. John Yule, re-elected president by acclamation; first vice-president, Mr. C. B. Hunt; second vice-president, Mr. J. A. Kammerer; secretary-treasurer, Mr. C. H. Mortimer, re-elected by acclamation.

The five members of the Executive Committee who were re-elected were Messrs. J. J. Wright, F. C. Armstrong, John Carroll, A. B. Smith and O. Higman. The five new members of the Executive Committee who were elected were, Messrs. F. A. Bowman, W. H. Browne, Wm. Thompson, A. A. Dion and W. Phillips.

MR. F. C. ARMSTRONG read his paper entitled, "Why Some Lighting Plants do Not Pay." After the paper had been read, a lengthy and heated discussion followed as to the respective merits of the flat rate and meter systems, each system having its champions. Mr. Browne strongly upheld the meter system. Mr. Armstrong was in favor of the meter system, but the difficulty in connection with small central stations, under the meter system, was to get a return for the outlay.

MR. NOXON spoke in favor of the flat rate system; he said a yearly contract could thus be more easily obtained, and the managers of stations were enabled to estimate their revenue.

MR. PEPLAR said that the trouble with the flat rate system was with regard to the load, as the consumption could not be checked. He stated that they now had a sort of combined plan, that of using the meter system with large consumers and a flat rate with small customers, and giving a reduction to large users. The majority of the members seemed in favor of the meter system.

MR. C. A. CARR, manager of the London Electric Railway, read a very interesting paper on "How Electric Railways Might be Made a Commercial Success."

MR. W. A. JOHNSON read a paper entitled, "Accumulators—Their Application to Central Station Lighting and Power." He stated that the cost and maintenance of storage batteries would not exceed from 3 to 5 per cent.; that the makers gave a guarantee of 10 per cent. at the outside.

MR. ARMSTRONG said that the use of storage batteries was restricted by being confined to direct current work.

MR. BROWNE stated that his method of overcoming that difficulty was by using a direct current machine to charge the battery and then using the current from the battery to operate a motor to drive an alternator.

MR. D. H. KEELEY'S paper entitled, "Economy in Circuits," was then presented.

This closed the business of the convention.

In the evening the annual banquet was held at the Dufferin Café; after the dinner had been served, the following toasts were given: "The Queen," "Our Guests," "Electrical Interests," "The Ladies" and "The Press," with which toast the name of Mr. W. J. Johnston, of "The Electrical World," of New York, was coupled, to which he replied in a few brief remarks.

The banquet was brought to a close by the singing of the national anthem, and was declared by all present to have been a decided success. The committee to whom was due the success of the banquet was composed of Messrs. E. E. Cary, chairman, F. C. Armstrong, W. Phillips, C. B. Hunt and A. B. Smith.

THE THIRD DAY was devoted largely to sightseeing; trips were taken over the Niagara Falls Park and River Railway and on the celebrated Gorge Electric Railway; and a visit of inspection was paid to the hydraulic power house. The Maid of the Mist took the members of the association to the foot of the Cataract, after which visits were made to the power house and works of the Cataract Construction Company and the various electro-chemical works.

Votes of thanks were passed to retiring officers, to authors of papers, to the press and to all those who had tendered courtesies, after which the convention adjourned to meet at Montreal in 1898.

AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

A preliminary programme of the proceedings of the Detroit meeting of the American Association for the Advancement of Science is to be issued by each of the sections before the middle of June. It is expected that the programme for Section B (physics) will include a number of electrical papers of especial interest, as it is becoming more and more customary for electricians to attend this meeting. Brief abstracts of papers to be presented before this section should be forwarded to its secretary, Dr. Frederick Bedell, Ithaca, N. Y., at the earliest possible date.

MUNICIPAL OWNERSHIP LEAGUE.

The American Municipal Ownership League of Brooklyn has been incorporated with the New York Secretary of State. The association is formed to advance and spread the doctrine of the municipal ownership of all railroads, public franchises, gas and electric plants, water works, etc. The directors are: Dayoe de Waltoff, Michael Russell, Bernard Cantor, Ferd W. Buermeyer, Nemesis Manassa, Thomas McCormick and John Kolb, of Brooklyn.

PERSONAL

SAMUEL INSULL.

THE new president of the National Electric Light Association, Mr. Samuel Insull, has the honor of being also the president of the Association of Edison Illuminating Companies. In each case, the office sought the man, and found a worthy recipient. Mr. Insull is the maker of his own career, the author of his own success, and yet is very far from having the air that tradition is wont to ascribe to the "self-made man." He is only 37 years old, and was born in England, where after receiving a good sound education he entered the office of the famous satirical publication "Vanity Fair." There he caught the discerning eye of Mr. E. H. Johnson, then introducing the Edison telephone in England. After a brief experience with early telephone work in England, in 1879, he came to America in 1881, and Mr. Johnson's recommendation brought him into Mr. Edison's personal service. His ability and quickness and his utter devotion to duty soon won him approval at hard working Menlo Park, and he was entrusted in short order with the management of Mr. Edison's affairs, with growing responsibility all through the stirring years that saw the upbuilding of the Edison Lamp Works, the Machine Works and Bergman's supply factory. As the result of the consolidation of these huge interests in the Edison General Electric Company, came the necessity of a new start, and Mr. Insull then created as by the waving of a wand the vast establishment of the Schenectady shops, familiar to readers of The Electrical Engineer, which described them in detail in 1891. The next big consolidation, that of Edison and Thomson-Houston interests, again saw Mr. Insull at the front of affairs, as one of the vice-presidents of the new General Electric Company; but the position was irksome and he resigned it, in order to accept the presidency of the Chicago Edison Company. Here again his executive ability displayed itself, and his mettle has been tried more than once as an organizer and financier since the panic of 1893, with the only result that the Chicago Edison Company is to-day one of the solidest and best handled corporations in the West. Of late, Mr. Insull has interested himself again in manufacturing, for which he has a strong predilection; and he is to-day not only connected with the General Incandescent Arc Light Company, of New York, but the new Fort Wayne Lamp Company, not to mention others.

Mr. Insull is a man of English stability and poise, but swift of speech and action, and alert far beyond even American ideals. He is unmarried, rises with the lark and is a total abstainer, but his cigar bill probably evens things up. He is loyalty itself to his friends and convictions, but his native reserve stands in the way of his making a very large circle of intimates. Mr. Insull was, while in New York, president of the Electric Club, to which he contributed with freehanded generosity. He is also a member of the American Institute of Electrical Engineers, taking the deepest interest in all technical matters. He is a member of several Chicago and New York clubs, and finds great pleasure in the social side of club life. Few American electrical men are so well known on both sides of the Atlantic.

MR SAMUEL INSULL.

MR. A. M. YOUNG.

THE new first vice-president of the National Electric Light Association is a typical American man of affairs. He is an old telegrapher, and may be said to have been interested in electricity all his life. He not only has large local lighting interests at Waterbury, but is prominent in at least a dozen lighting and railway enterprises in various parts of the Union. He is also the president of the New England Engineering Company, which has done a great deal of electrical construction work. Last year Mr. Young was a member of the Executive Committee of the N. E. L. A., and his advancement in the affairs of the association is a well-deserved honor.

MR. A. M. YOUNG.

MR. C. D. WARNER, recently with the Iron Clad Rheostat Company, of Westfield, N. J., has entered the service of Mr. D. McF. Moore, at the Moore Laboratory, Newark, N. J. Mr. Warner is a graduate of the University of Nebraska, Electrical Engineering Department.

MARSHALL, TEXAS.—Mr. E. L. Wells, manager and purchasing agent of the Arkansas and Texas Consolidated Ice and Coal Company, writes us: "We like The Electrical Engineer—'tis a mighty good paper."

MR. T. E. FLEMING, the admirable secretary of the Telegraphers' Mutual Benefit Association, has resigned in order to become assistant to Secretary Bruch, of the Postal Telegraph-Cable Company. Mr. Fleming finds an excellent successor in Mr. M. J. O'Leary, and has received a set of highly laudatory resolutions from the T. M. B. A.

OBITUARY

S. G. HESS.

We regret to note the death of Mr. Seymour Griswold Hess, son of Subway Commissioner Hess, of New York City. He was only 26 years old and succumbed to pleuro-pneumonia, which first attacked him while acting. After leaving the Columbia Law School he entered the law office of his uncle, Mr. C. A. Hess, but went on the stage and there soon made his mark as a clever light comedian, as well as a composer and musician. He had a great many friends in electrical circles, where his sudden death is deeply lamented.

LEGAL NOTES

MANHATTAN GEN. CONS. CO. vs. JANDUS ELEC. CO.

A petition was filed in the United States Circuit Court, Cleveland, Ohio, on June 12, by the Manhattan General Construction Company against the Jandus Electric Company for violating a contract agreement, and endeavoring to ruin the business of the Eastern company. The plaintiff company also declares that the Jandus Company has endeavored to secure the services of one of its officials for the purpose of having him turn over his knowledge to the Cleveland corporation. A writ of injunction is asked, provisionally enjoining and restraining the Jandus Electric Company from refusing and failing to carry out the provisions of the agreement; to restrain the Jandus Company from selling certain arc lamps, and to enjoin the defendant from publishing statements to customers of the Manhattan Company. On Thursday Judge Hammond, of the United States District Court, sitting at Toledo, will hear the application for a temporary injunction. The Manhattan Company has handled the Jandus enclosed arc, and claims that the Jandus company seeks to cut off the supply and get the business that has been built up.

INDIANA THREE-CENT-FARE LAW VALID.

The Supreme Court of Indiana has decided that the three-cent car fare law is constitutional. It relates to Indianapolis only. In the Federal court recently the same law, passed by the last Legislature, was declared unconstitutional, and injunctions were granted by Judge Showalter against its enforcement. The State will insist on three-cent fares unless the street car company secures injunction pending appeal to Federal Supreme Court. In the Hammond cases recently, where the State Supreme and the Federal court differed, the Supreme Court of the United States held that it was not its policy to enter into conflict with the Supreme Courts of States. On this Attorney General Ketcham thinks the three-cent fare law will stand, but that five-cent fares will be collected until Judge Showalter modifies his order, which he doubtless will do.

RESTRAINED FROM SELLING WALKER PLANS.

Judge Taft, of the United States Circuit Court, at Cleveland, on June 7, granted a temporary injunction, on the application of the Walker Manufacturing Company, to restrain W. H. Bone and R. T. Bone, respectively acting secretary and manager and assistant secretary of the company, from selling or giving to a rival company plans and tracings of inventions owned by the company. The Walker Company manufactures machinery for electric railways and it asserts in its petition that plans which cost $50,000 have been taken by the defendants with the intention of giving them to a rival.

REPORTS OF COMPANIES

WESTERN UNION TELEGRAPH CO.'S QUARTERLY SHOWING.

The Western Union Telegraph Company has declared a quarterly dividend of 1¼ per cent., payable July 15. The earnings for the quarter ended June 30, partly estimated, compare as follows with the actual figures of the corresponding period last year:

Net revenues	$1,550,000	Inc.	$149,800
Interest and S. F.	203,875	Inc.	371
Balance	$1,346,125	Inc	$149,429
Dividend	1,216,975	Inc.	25,016
Surplus	$129,150	Inc.	$124,413
Previous surplus	7,559,748	Dec.	79,200
Total surplus	$7,688,898	Inc.	$45,204

The June quarter completes the fiscal year of the company, and the results, partially estimated, compare as follows with the figures for the previous year:

Net revenues	$5,772,520	Dec.	$125,466
Interest and S. F.	934,455	Inc.	498
Balance	$4,838,065	Dec.	$125,958
Dividends	4,792,862	Inc.	25,057
Surplus	$845,203	Dec.	$151,615
Previous surplus	7,643,694	Inc.	196,218
Total surplus	$7,688,897	Inc.	$45,203

The company is to list $2,000,000 of treasury stock against improvements, representing about double that amount. The capital is now $100,000,000, now nearly all issued.

THE STOCK MARKET

"THERE'S A GOOD TIME COMING."

THE sentiment that is expressed in the headline has been heard frequently of late, with not less numerous disappointments attending, but every day brings nearer, with definite surety, normal seasons of activity and prosperity, and hopefulness is now more apparent and genuine than at any other period during the last five years. There may be further delays and drawbacks, but the rising tide will presently swamp all barriers.

Last week witnessed a genuine revival in the stock market based on improved railway returns, and the sale of bonds showed a noteworthy increase. Stock prices were also much better. General Electric rose from 31 to 33⅛, and even touched 34⅛. Western Union crossed the 80 line again and went to 81¾ on sales of 61,720 shares. American Bell was active around 230 to 231. Local lighting and railway securities also gave proof of a better inquiry and sale.

COPPER is quoted, Lake at 11½, and Western at 11¼.

STEEL RAILS, heavy section, are quoted at $19 rising, and light rail, $24 to $28.50, according to section.

MISSOURI INDEPENDENT TELEPHONE COMPANIES MEET.

A special dispatch from Sedalia, Mo., of June 7, says: Representatives of the Independent Telephone Line of Missouri held a secret conference this afternoon in the parlors of Kaiser Hotel. A. W. McArthur, of Kansas City, who furnished the information for the press, stated that the delegates present reperesented all Missouri lines not controlled by the Bell Company, and the conference was in regard to telephone business in general. There have been reports that certain lines now operated independently are to fall into the hands of the Bell Telephone Company, and to prevent such action was one of the objects of the meeting. H. E. Ralston, Maryville; A. W. McArthur, Kansas City, and E. C. Baker, Cameron, were elected delegates to the National Convention of Independent Telephone Lines to be held at Detroit, Mich., June 22, after which the conference adjourned.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JUNE 8, 1897.

Alarms and Signals:—

HOTEL ELECTRIC CALL APPARATUS. A. B. Chance, Centralia, Mo., 584,173. Filed November 23, 1896.

Combines call, telephone and fire alarm apparatus.

BURGLAR ALARM SYSTEM. W. T. Arnold, Chicago, Ill., 584,202. Filed December 15, 1896.

A burglar alarm system in which districts located in various places are connected with signal devices at a central office.

NON-INTERFERING SIGNAL BOX. J. T. Stack, Chicago, Ill., 584,297. Filed September 29, 1890.

Details of construction.

Batteries, Secondary:—

SECONDARY OR STORAGE BATTERY. A. S. Krotz, Springfield, Ohio, 583,912. Filed March 27, 1894.

Supporting plates formed of insulating material and having slotted openings with upturned edges, and electrodes formed of active material arranged between the upturned edges and openings, the plates being arranged one above the other with the slotted openings in one plate in line with the electrodes of the adjacent plates.

Conductors, Conduits and Insulators:—

FEED WIRE CONNECTION. S. H. Harrington, New York, and G. E. Somers, Bridgeport, Conn., 583,903. Filed April 8, 1897.

A connector for underground trolleys consisting of a plug secured in the rail and a plurality of flattened wires adapted to engage with a feed wire.

CONDUIT. J. T. McRoy, Chicago, Ill., 583,926. Filed March 22, 1897.

A series of sections laid end to end and each provided with longitudinal ducts and dowel-openings formed in the ends of the intersecting partition-walls of the ducts, of metallic dowel-pins arranged in the openings.

INSULATOR FOR TELEGRAPH OR OTHER ELECTRIC WIRES. C. V. Nesmith and G. F. Arnett, Manchester, Ala., 584,235. Filed March 27, 1897.

Comprises two separate parts intended to receive the wire between them and a set screw for holding the wire in place.

CONNECTION FOR ELECTRICAL CONDUCTORS. B. F. Weldon, Pittsburg, Pa., 584,299. Filed May 5, 1897.

Comprises an inclosing envelope surrounding the wires, and bent transversely.

Distribution:—

SYSTEM OF ELECTRICAL DISTRIBUTION. J. L. Woodbridge, Brooklyn, N. Y., 583,029. Filed November 13, 1895.

Means for enabling a generator to be used either as a constant potential machine for supplying energy to bus-bars or as a booster in series with a feeder.

Dynamos and Motors:—

ELECTRIC MOTOR. E. S. Pillsbury, St. Louis, Mo., 583,933. Filed November 16, 1895.

Comprises the field magnets, a progressively wound armature, a commutator, a closed winding on the armature, means for short-circuiting the progressive windings of the commutator, and a switch in the motor circuit operated by said means.

BINDING BAND FOR ARMATURES. H. Geisenhoner, Schenectady, N. Y., 583,991. Filed October 31, 1896.

A metal strip with wedges secured to its extremities, clamps provided with inclined surfaces engaging with similar surfaces on the wedges, and means for securing the clamps together.

Electro-Metallurgy:—

ART OF WELDING AND BRAZING. D. W. Payne and E. Diven, Elmira, N. Y., 584,120. Filed October 26, 1896.

Adapted for the treatment of metals of different characteristics.

PROCESS OF MAKING COMMERCIAL LEAD FROM LEAD ORES. P. G. Salom, Philadelphia, Pa., 584,242. Filed May 15, 1893.

The ore is subjected to the action of nascent hydrogen, electrolytically developed, producing thereby a spongy mass, and afterward, while the mass is in a non-oxidized condition, applying a consolidating pressure thereto.

Lamps and Appurtenances:—

SEARCH LIGHT MOUNT. F. T. & G. E. Marschand, Annapolis, Md., 583,916. Filed September 21, 1896.

Consists of a column revoluble about its vertical axis, a stationary base supporting the column, a platform surmounting the column and capable of angular displacement around a horizontal axis.

ELECTRIC LIGHT FOR VEHICLES. A. M. Rodriguez, Brooklyn, N. Y., 583,945. Filed October 7, 1896.

Adapted for bicycles. The current is supplied from a dynamo driven by a wheel.

CARBON HOLDER FOR ARC LAMPS. E. Thomson, Swampscott, Mass., 583,955. Filed Oct. 31, 1896.

Is provided with an eccentrically-pivoted rotary jaw, having a number of faces, a movable jaw, and means for clamping the same in a desired position.

SAFETY LAMP. W. Waegel, Philadelphia, Pa., 583,959. Filed September 5, 1896.

Comprises a hermetically sealed glass casing, containing a non-inflammable gas, around the lamp, and means whereby the current is shut off when the lamp is broken.

ELECTRIC ARC LAMP. G. L. Moyer, Hartford, Conn., 584,184. Filed October 22, 1896.

Feed mechanism for enclosed arc lamps.

ELECTRIC ARC LAMP. G. L. Moyer, Hartford, Conn., 584,186. Filed January 20, 1897.

Of the enclosed arc type.

Measurement:-

SHUNT AMMETER. W. B. Potter, Schenectady, N. Y., 583,934 Filed January 25, 1897.

Consists of a plurality of ammeters connected in shunt to a common resistance.

THREE-PHASE INDUCTION METER. C. P. Steinmetz, Schenectady, N. Y., 583,950. Filed January 30, 1897.

Details of construction.

ELECTRIC METER. J. Harris, Lynn, Mass., 584,900. Filed November 25, 1895.

A speed governor consisting of a rotatable fan connected to a source of power and a movable contact arranged so that at predetermined speeds the fan will press against the movable contact and operate.

MOTOR-METER. Chas. P. Steinmetz, Schenectady, N. Y., 583,951. Filed Jan. 30, 1897.

An inductive device for obtaining a definite phase displacement between a circuit and a branch, consisting of two windings having different number of turns inductively related upon a common core, the windings being included respectively in branches of the circuit.

Miscellaneous:—

ELECTROSTATIC INFLUENCE MACHINE. E. Thomson, Swampscott, Mass., 583,957. Filed January 5, 1897.

Comprises a charging exciter-plate provided with an equalizer and a pair of sector charging collectors connected to the sectors of the charging-plate, and the sectors of the working plates of the machine, the exciter having no connection with the working circuit.

ELECTRIC FURNACE. E. F. Price, Niagara Falls, N. Y., 583,936. Filed September 23, 1896.

Embodies a hearth forming one electrode, and carbon electrodes placed over it, the material being supplied through a hopper.

APPARATUS FOR PRODUCING CURRENTS OF HIGH FREQUENCY. N. Tesla, New York. 583,953. Filed October 19, 1896.

A modification of previous apparatus for converting low tension into high frequency apparatus. The condenser is subdivided and charged in multiple and discharged in series.

PRODUCING STEREOSCOPIC PICTURES BY ROENTGEN RAYS. E. Thomson, Swampscott, Mass., 583,956. Filed January 5, 1897.

Consists in exposing the object to a source of Röntgen rays in one position, and then shifting the relative positions of the source of rays and the object.

SYNCHRONIZING CLOCK. J. H. Gerry, Brooklyn, N. Y., 584,128. Filed March 11, 1896.

Method of synchronizing the second hand.

PROCESS OF AND APPARATUS FOR AGEING ALCOHOLIC LIQUIDS. H. Deininger, Berlin, Germany, 584,050. Filed November 1, 1895.

Consists in first impregnating the liquid with oxygen, and then subjecting it to the action of an alternating current of electricity.

IGNITING DEVICE. B. Jolles, Vienna, Austria-Hungary, 584,056. Filed February 1, 1897.

The valve for admission of gas is opened by an electromagnet.

SYNCHRONIZING MECHANISM. H. F. Parshall, London, Eng., 584,062. Filed December 31, 1895.

Consists in controlling the speeds of the different generators by means of acting upon their prime movers and actuated by the variations of phase relation between the generators.

THERMOSTAT. H. Van Hoevenbergh, New York, 584,249. Filed January 16, 1895.

Comprises a slender metallic wire extending through a non-conducting casing closely embracing it, the conductor being fixed at one end and co-operating with a detent at the other.

Railways and Appliances:—

RAIL-BOND. S. H. Harrington, New York, and G. E. Somers, Bridgeport, Conn., 583,902. Filed March 19, 1897.

A shoulder near its end and a separate sleeve adapted to slip over the end and to bear against the shoulder, one end of the sleeve being diagonal to its axis.

SERIES PARALLEL CONTROLLER. W. B. Potter and F. E. Case, Schenectady, N. Y., 583,935. Filed October 10, 1896.

Comprises a plurality of stationary contact brushes, moving contacts engaging therewith, and a plurality of blow-out-magnet coils each included in a separate circuit.

PNEUMATIC CONTROLLER. E. D. Priest, Schenectady, N. Y., 583,938. Filed September 18, 1896.

Comprises a plurality of separate pneumatically operated contacts, with a valve for regulating their operation.

PNEUMATICALLY ACTUATED CONTROLLER. E. D. Priest and F. A. Merrick, Schenectady, N. Y., 583,939. Filed September 28, 1896.

Similar to above.

TURN TABLE FOR SURFACE CONTACT ELECTRIC RAILWAYS. E. M. Hewlett, Schenectady, N. Y., 583,997. Filed November 18, 1896.

Employs permanent contacts of opposite polarities, exposed studs upon the turn table, and intermediate contacts operating by the rotation of the exposed studs and the permanent contacts thereby to reverse their polarities.

RAIL-BOND. W. B. Potter, Schenectady, N. Y., 584,013. Filed December 18, 1896.

Comprises roughened plates, a conductor connecting the plates, a plastic compound of good conductivity filling the roughened portion of the plates and means for securing the plates to the rails.

PREPAYMENT MECHANISM FOR ELECTRICAL OR OTHER METERS. Charles O. Bastian and Herbert C. Hodges, London, England, 584,258. Filed August 17, 1896.

Adapted to be operated by an exterior handle on the insertion of the proper coin.

Regulation:—

ELECTRIC REGULATOR. C. C. Gartland, Buffalo, N. Y., 584,155. Filed September 4, 1896.

A device operated by the diaphragm to control a rheostat.

Switches, Cut-Outs, Etc.

ELECTRIC SWITCH. G. Winckler, Schenectady, N. Y., 583,963 Filed June 4, 1896.

Double-throw knife switch.

LIGHTNING ARRESTER. A. Ekstrom, Schenectady, N. Y., 583,987. Filed May 15, 1896.
Comprises a number of spark-gaps in series, of a kind to have their resistance decreased by use, combined with means controlled by such decrease in resistance, for increasing the number of spark gaps in series.
SAFETY PLUG. T. S. McClintock, Pittsburg, Pa., 584,009. Filed August 5, 1896.
Details of construction.
AUTOMATIC ELECTRIC TIME SWITCH. L. H. Watters, Media, Pa., 584,149. Filed April 1, 1896.
Details of construction.
CUT-OUT SWITCH. G. L. Moyer, Hartford, Conn., 584,185. Filed November 18, 1896.
Details of construction.

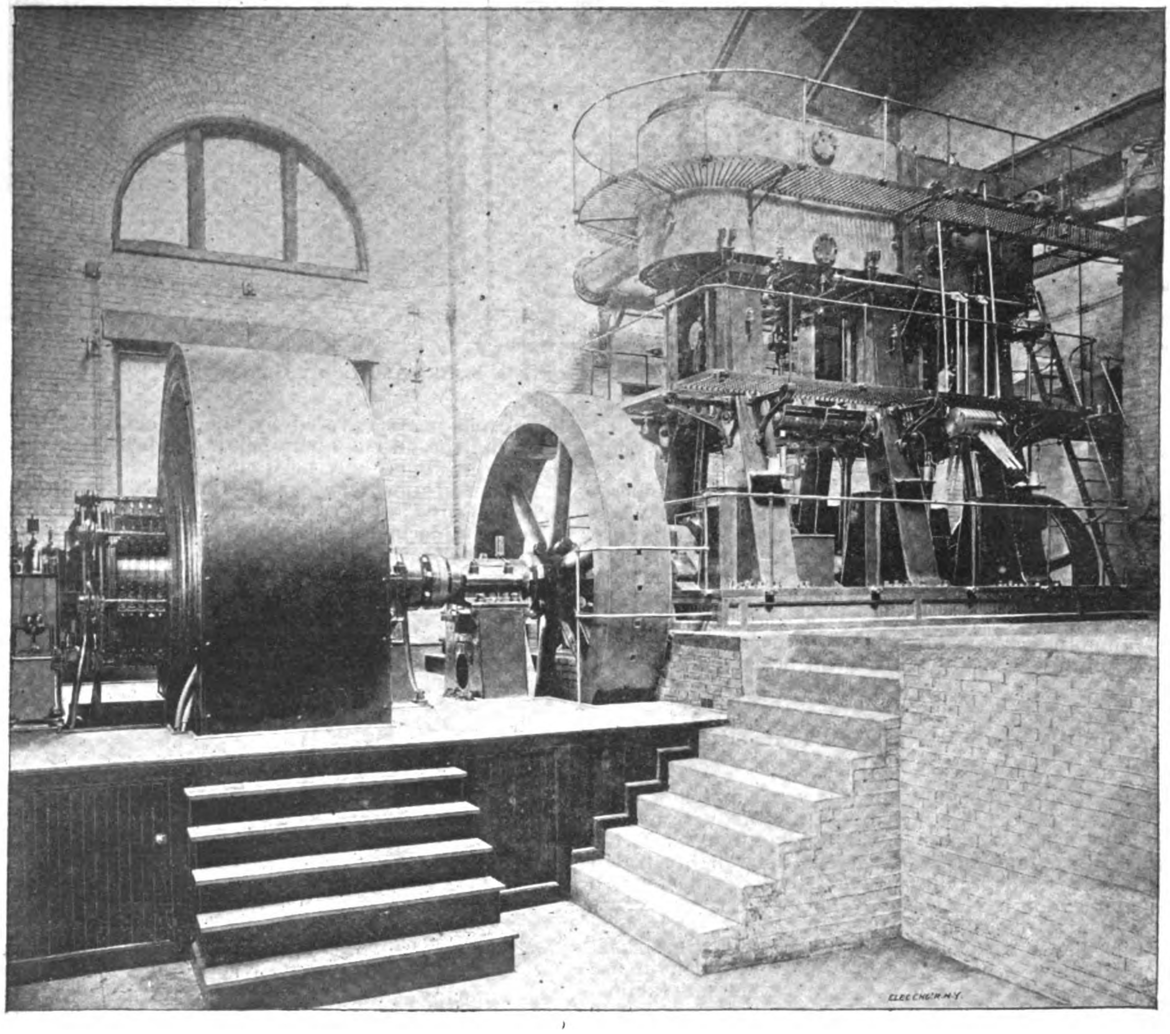
Transformers:

ROTARY CONVERTER. E. W. Rice, Jr., Schenectady, N. Y., 583,944. Filed March 14, 1896.
An armature of the alternating current type, comprising winding and collecting rings, each collecting ring connected to leads equally spaced around the armature winding and connecting equipotential points of each phase to one of the collecting rings.

TRADE NOTES & NOVELTIES

ELWELL-PARKER 1200 H. P. RAILWAY GENERATOR.

THE Elwell-Parker Electric Company, of Cleveland, O., whose motors were illustrated in our last issue, also build generators of large power. The accompanying engraving illustrates a generator built for and installed by the Cleveland City Railway Company. It has been in continuous service for about 22 hours a day for 17 months, during which time it has cost nothing for repairs. There is no sparking on any load within the capacity of engine up to 1,500 horse-power, and the position of the brushes on the commutator has remained fixed and unchanged ever since the machine started, 17 months ago. The bearings are oiled by little force pumps (mounted on the bearing) insuring a sure and continuous oiling of the bearings and a constant and continuous straining of the oil which is thus always clean and thus greatly economized. The commercial efficiency is 96 per cent. between coupling and terminals. The engine is a vertical triple condensing built by the Globe Iron Works Company, of Cleveland. The all-round efficiency and commercial economy of this generating plant is claimed to be unsurpassed in railway work.



Elwell-Parker 1,200 H. P. Railway Generator, Cleveland City Railway Co.

THE GARTLAND REGULATOR FOR CONSTANT CURRENT SERIES ARC MACHINES.

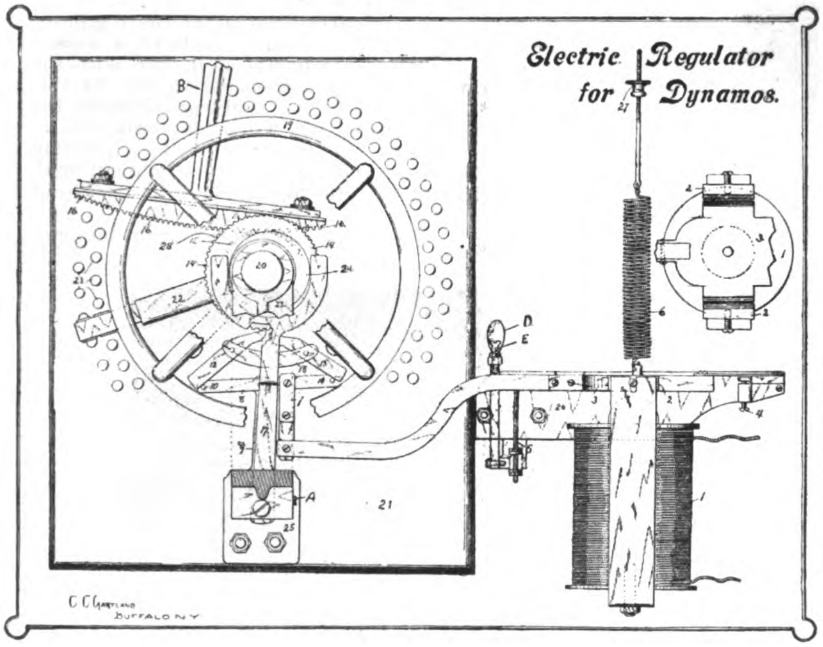
AMONG the exhibits at the N. E. L. A. convention, at Niagara, was the Gartland regulator for series arc machines.

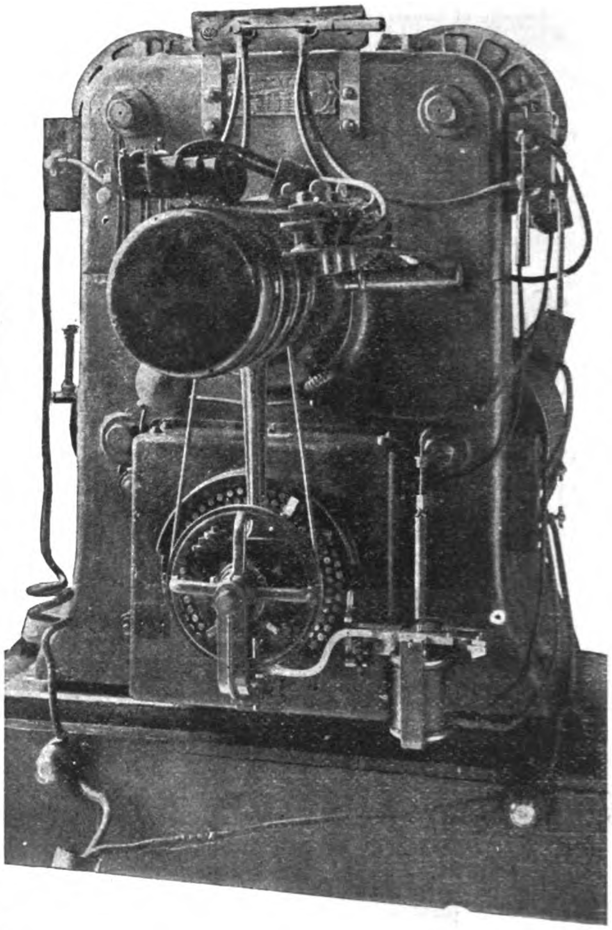
Fig. 1 shows the regulator attached and in working order, while Fig. 2 shows the general arrangement of the regulator in which (1) is the spool which is wound to have a power sufficient to hold the armature (3) balanced in line with the poles (2), acting of course against tension spring (6). In this condition the armature is maintained midway between the stops (5), and the rocking lever (8), which is connected to armature by connecting link (7), is maintained in position which supports the pawls (12 and 13) out of engagement with the ratchet wheels (14 and 14), and the whole is in a state of equilibrium.

If now the current of the dynamo decreases, from increase of load or otherwise, the decreased power of the spool will allow the armature (3) to be lifted by the tension spring (6), and this will rock the lever (8) and allow the pawl (12) to engage the ratchet wheel (14).

The constantly oscillating arm (17) will then cause the pawl to move the ratchet (12) toward the right and slightly move the brush rocker the opposite way and at the same time rotate the gear which meshes with the rack (16), and this will move the rheostat arm (22) to which the gear and ratchets are all three secured by screws.

This regulator may also be applied to constant potential regulation in the same manner, the spool being wound according to the e. m. f. required. It may also be applied to the regulation of alternating current machines, as well as to separately excited machines generally, by connecting the rheostat in series with the field coils of the exciting machine, and in the case of the alternating machine, preferably connecting the spool in the secondary circuit from a transformer in which circuit a second rheostat operated by a spool in the primary circuit of the alternator is also interposed; this same amount of current (and, hence, of strength) with 110 volts potential around it as at 100 volts, thus automatically taking care of the line loss on primary circuit in exact proportion to the loss, at all variations of load. When used to regulate the speed of machinery the arm is connected to any suitable speed governor, and electric current is supplied to the spool from any convenient source.





Figs. 1 and 2.—The Gartland Regulator for Series Arc Light Generators.

It has no sparking contacts to become oxidized and inoperative, no wall controller, no shunt coils or circuits, and when it is once adjusted to the desired current, it will always remain so, making it unnecessary to interfere with it at any time when starting or stopping the generator, being perfectly controlled by the current generated in the machine. The combined movements of rheostat and brushes are operated with such promptness than an increase or decrease of about one-tenth of an ampere in the circuit will bring the regulator into action.

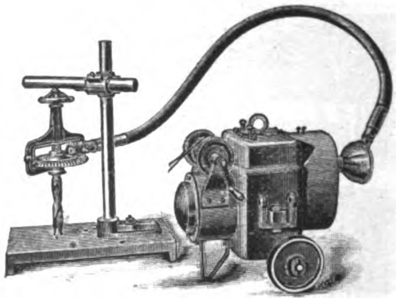
STOW FLEXIBLE SHAFT AND ELECTRIC MOTOR COMBINATION.

The combination of the Stow flexible shaft and new iron-clad electric motor, designed and manufactured by the Stow Manufacturing Company, of Binghamton, N. Y., as adapted to drilling, tapping, reaming, etc., is well illustrated in the accompanying engraving which tells its own story so far as the application is concerned. The motor, however, requires more detailed mention.

The combination of an electric motor with a flexible shaft for the performance of this class of work, has been in use for some years and, in the main, has given good satisfaction. There yet remained, however, some improvements needed to bring this combination to practical perfection as voiced in the demand which has sprung up for a dust and waterproof motor, which this new iron-clad motor has been designed to meet.

The frame of this motor is in the form of a hollow cube, with inwardly projecting poles. In each end of the frame is a circular aperture, over which are bolted the end plates supporting the bearings. One of these is extended into a short cylinder forming a case for the commutator and brush holder. The field coils are protected by metallic cases and can be easily removed. The motors below 2 h. p. are bi-polar and those of 2 h. p. and over have four poles. The best of material is used in construction. The bearings are self-oiling; mica insulation is used, and the rheostats protected by an iron case, and gears covered by simply changing the end plates to bring the oil chambers below the bearings; this motor can be run in almost any position.

Motors of this type can be furnished for direct connection when desired, also for electric street railway track drilling. The portable motors, as shown, are fitted with truck wheels, leg, eye-bolt, side brackets, reel, 20 yards of insulated wire, and



The Stow Flexible Shaft and Motor.

one set of reduction gears. By use of speed regulator and gears, almost any practical speed can be obtained. Either the company or their European agents, Messrs. Selig, Sonnenthal & Co., 85 Queen Victoria street, London, E. C., England, may be addressed for prices or for further information.

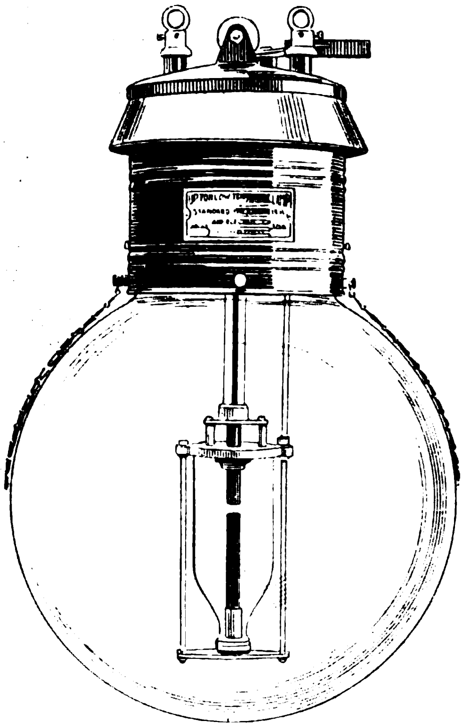
FORT WAYNE LAMP CO.

An important piece of news is the formation of the Fort Wayne Lamp Company, which has just been incorporated with a capital stock of $100,000. The directors in the new company are R. T. McDonald, Samuel Insull and H. J. Miller.

The company's plant and property consist of those bought recently from the Adams-Bagnall Company, of Cleveland, O., which sold out all its incandescent lamp business to Messrs. McDonald and Insull. One of the notable "talking points" of the lamp is the absence of a sealing nipple, and the consequent smooth finish of the bulb. It is understood that the lamp is to be made in the best possible style of the art, and to be very vigorously pushed.

THE UPTON "MIDGET" ENCLOSED ARC SERIES LAMP.

In comparing the efficiency of enclosed arc with open arc lamps for service on street lighting and commercial circuits, the question of their respective candle-powers is naturally an important consideration. While it is true that with an enclosed arc the candle-power is lessened somewhat, actual experience has proved that this loss is more than counter balanced by the gain in steadiness of light, equality of diffusion and absence of shadow in the use of an enclosed arc over an open arc lamp; especially in the high tension series lamp has this fact been developed.



The Midget Enclosed Series Arc Lamp.

The Upton "Midget" enclosed arc series lamp, manufactured by the Standard Thermometer and Electric Company, of Peabody, Mass., embodies in its mechanism all that is best and simple in the recent development of arc lamp construction. It is designed so it can be easily adjusted to take from 65 to 80 volts as may be desired and burn on from 4½ to 7 ampere circuits without readjustment. Each lamp is provided with a switch, and an automatic cut-out which is positive in its action. These lamps are now in use on street lighting and commercial circuits, and the manufacturers claim to have flattering reports of their successful operation. Full information and circulars will be furnished by them on application.

CENTRAL ELECTRIC CO. AND FOREIGN TRADE.

It is quite rare that wholesale houses located at inland points enjoy much foreign trade, but a notable exception can be found in the Central Electric Company, of Chicago, who state that for some time they have had quite a large trade with points in Japan as well as South America, and quite recently they received a very large order from South Africa, which was secured by submitting quotations in competition with other places.

V. J. MAYO, 100 North Clinton street, Chicago, reports that he has received some nice orders for the "Mayo" alternators, and that he is having a number of inquiries right along. He is very hopeful of making some more good sales in the near future.

THE O. K. DRY BATTERY.

The Non-Polarizing Dry Battery Company, of 347 West Broadway, New York, are well satisfied with the remarkable success of their O. K. dry battery. The company now number among their customers all the leading railroad companies, who use this battery for their signal and grade crossing work. The leading gas engine companies also find in the O. K. battery a great saving both in actual cost of the battery and in the reduced bills for attendance. A number of telephone companies have also found the O. K. battery to be just what they have been looking for.

THE O. K.
Dry Battery
MANUFACTURED BY
THE NON-POLARIZING
DRY BATTERY COMPANY
347 W. Broadway, New York
For use in open-circuit work of all kin
including Electric Gas Lighting, Electric Bells, B
lar Alarms, Telegraph, Telephones, Ann
ators, Door Openers, Railway Signals, Me
Apparatus, and wherever a strong, durable, and
quickly recuperating battery is needed.

The O. K. Dry Battery.

THE GRAVES ENCLOSED ARC LAMP.

Our illustration represents one of the various types of enclosed arc lamps manufactured by the W. D. Graves Electric and Machine Works, of Cleveland., O. This lamp, designated as their No. 99, is made for 110-volt circuits, or will run two in series on 220 volts, or five in series on 500 volts. The company guarantee perfect regulation, and the lamp is arranged to pass from 4 to 5½ amperes, as desired, with a potential of 80 volts at the carbon points.

The Graves Enclosed Arc Lamp.

Any of the long burning lamps of the Graves Company are adapted for constant current circuits of 6½ amperes. The lamps are finished in polished brass, oxidized brass, oxidized copper, or nickel, and are very ornamental.

ADVERTISERS' HINTS

THE STANLEY ELECTRIC MANUFACTURING COMPANY'S San Francisco office is now at 300 California street.

THE DIAMOND ELECTRIC COMPANY, Peoria, and Fisher Building, Chicago, Ill., illustrate and point out the advantages of the well-known Diamond transformers and Scheeffer's wattmeters. These have both made a reputation for themselves and are daily enlarging it.

HENRY F. NOYES, 56 Liberty street, New York, has undertaken a correspondence course of instruction in patent office practice for inventors and business men and invites those interested to write for particulars.

THE J. I. CASE T. M. COMPANY, Racine, Wis., claim the Raymond improved gas and gasoline engines, 1 to 100 h. p., to be unexcelled in efficiency for driving electric light and stationary power plants.

JACQUES ULLMANN, 16 Boulevard St. Denis, Paris, France, requests illustrated price lists concerning the electrical trade. He refers to the Bradstreet Company and the Crocker-Wheeler Electric Company, New York.

V. J. MAYO & CO., 100 North Clinton street, Chicago, pronounce their alternators a success. They are built for any voltage, speed, frequency or number of phases; the armature is stationary and coils are easy to replace; the efficiency is claimed to be 94 per cent. or better.

J. G. BIDDLE, advertises the "Bowdoin" X-ray focus tube. They are made in two styles at prices respectively $6 and $7.50, and will be shipped immediately on receipt of order.

THE WALKER COMPANY, are of the opinion that the public needs a new arc lamp that may be truly considered a superior production and they are further of the opinion that the new Walker lamp is just the one to fill the need.

THE STOW MANUFACTURING COMPANY, Binghamton, N. Y., advertise the combination of the Stow flexible shaft and iron clad electric motor. It is described elsewhere in this issue.

THE ELECTRIC APPLIANCE COMPANY, 242 Madison street, Chicago, are sending free samples of the "Highland" soldering paste and remind their friends that it costs nothing to give it a trial.

THE ANCHOR ELECTRIC COMPANY, Boston, Mass., state that their improved push button switches are durable and require but little power to operate them.

THE REPLOGLE GOVERNOR WORKS, Akron, Ohio, advertise their new relay returning water wheel governor as representing the most efficient, accurate and satisfactory type ever placed on the market.

THE AMERICAN DISTRICT STEAM COMPANY, Lockport, N. Y., publish the happy results obtained by another central station using the Holly system of heating by exhaust steam.

THE H. T. PAISTE COMPANY, Philadelphia and Chicago, make some very pithy remarks on things in general and their switches, cut-outs, etc., in particular.

THE GARTON-DANIELS ELECTRIC COMPANY, Keokuk, Iowa, say the sales of their lightning arresters have doubled this year over last, and give a list of well known companies employing their apparatus.

NEW ENGLAND NOTES

THE HART & HEGEMAN MANUFACTURING COMPANY have issued catalogue "C," describing and illustrating their new line of the well known and popular Hart switches. Dimensions of switches are given in detail; wiring diagrams are given for three-way, four-way and electrolier switches; special switches, such as "Two-circuit," "No. 9" and "Dinner switch," are described. Full and interesting information is given regarding Hart flush switches and switch boxes. All interested in switches will find much profitable and interesting information in this catalogue, and should write for a copy if not already supplied with one.

SCRANTON, PA.--The Berlin Iron Bridge Company, of East Berlin, Conn., are erecting a new roof for the power station of the Scranton Illuminating Heat and Power Company, of Scranton, Pa. The building is 42 feet wide and 195 feet long, divided into two portions; a boiler room and an engine room. The framework of the roof construction is of steel and absolutely fireproof. It has been the aim of the Scranton Company to erect a substantial and fireproof building, to replace the one which they recently lost by fire.

DICK, KERR & CO., LTD., London, have inaugurated their new electric railway department under Mr. W. Rutherford, by taking a contract for the complete equipment of the Dover Corporation Tramways.

THE COMPAGNIE D'ELECTRICITE, of Nancy, France, now furnishing current for lighting and power to an extended territory, is about to enlarge its area of work, by the installation of two direct current units of 400 k. w. each. The construction of this work will be carried out by the firm of Fabius Henrion, of Nancy.

ROENTGEN RAY DIFFUSION PHENOMENA.

BY PROF. ELIHU THOMSON.

IT is well known that many substances subjected to the radiation from an excited Crookes tube diffuse the Röntgen rays received by them. It is known also that the diffusive action takes place throughout the substances or media, or that they are turbid in relation to the rays. It is probably owing to this that such substances as paraffine, wood, etc., possess apparently greater diffusive power than denser materials like heavy metals. With the latter, when the surface is smooth, there appears to be a tendency to regular reflection as demonstrated by Prof. Rood, of Columbia University, New York, and what diffusive action is noted is most marked near those directions which denote regular reflection. A mass of crystals of tungstate of calcium appears to be so devoid of diffusive action as to give no discoverable effect of diffusion. This is probably owing to the conversion of the energy of the rays into ordinary light, leaving no diffusive effect on the rays themselves. The diffusion is, so to speak, light itself. Barium platino-cyanide is feebly diffusive.

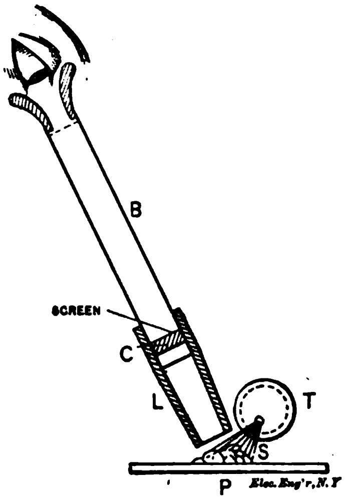

FIG. 1.

By the use of a form of Crookes tube devised by the writer for obtaining strong radiation, tests of diffusive action are rendered comparatively easy and simple. The tube referred to is one in which the glass wall closely surrounds the platinum target, so that it is easy to work very close to the bombarded spot, especially if a magnet be used to deflect the spot toward the edge of the platinum and near the glass wall.

With such a tube placed horizontally the rays emitted may pass immediately to the object or substance to be tested. A piece of heavy sheet lead, which has but very slight diffusive action, is provided. Upon this lead plate and in the most favorable position for receiving the rays is placed the substance to be tested, either in the form of a lump, slab or mass of crystals or granules. For liquids, such as oils or water, etc., a small but rather deep cup of lead is a convenient receptacle.

To observe the diffusive rays the fluorescent screen is required to be thoroughly protected from the direct rays of the tube. The writer has used a piece of heavy brass tube about 8 inches long, upon one end of which is fitted a wooden eye cap fitting closely around the eye and blackened, while the other end of the tube is stopped by a cork carrying fluorescent material on the face within the tube. The face of the cork turned toward the eye end is, in fact, coated with a varnish carrying barium platino-cyanide, which is more active than calcium tungstate. The end of the tube which has the cork screen fitted into it is now elongated by a heavy lead extension as a piece of lead pipe covering about an inch or two of the brass tube and surrounding, therefore, the cork screen and extending downward about 2 to 3 inches beyond the end of the brass tube. The lower end of the lead tube may be narrowed with advantage.

The whole arrangement is shown in Fig. 1, where T is the narrow part of the Crookes tube; S the substance to be tested resting upon a lead plate, P; B is the brass tube with its expanded eye end; C the cork screen; L the lead shield preventing direct rays reaching the screen. These parts may be clamped in relative position, with the lead plate, P, removable for substitution of other substances.

The writer has long had it in mind to discover, if possible, whether the diffused rays from a substance had the power of again undergoing diffusion. This may be termed secondary diffusion, to distinguish it from the ordinary or primary diffusion. Some trials made many months ago showed the futility of attempting to get any results except when working at short range with the most intense source, and with the most effective shielding. When it is remembered that at best it can only be that a very small percentage of the original rays will be emitted as primary diffusion in any particular direction, and that the secondary diffusion will be on a similar small percentage of the first or primary effect, the great delicacy of such a test can be imagined. The writer succeeded, however, in fully satisfying himself that secondary diffusion does take place. He was enabled to strongly irradiate a block of paraffine, receive the rays therefrom upon a second block and note the feeble illumination of a screen by the secondary diffusion from the second block. The removal of the second block, or the first block, or both, left the screen entirely dark.

The apparatus is a modification of that shown in Fig. 1, and is shown in Fig. 2. Here S^1 is the first block under the strongest rays from tube T. Diffusion takes place upward from S^1 within the heavy lead tube or shield, L, into the upper end of which is inserted the second block, S^2. Both pieces, S^1 and S^2, are cut on a slant or wedge-shaped to favor the action. The brass screen tube, B, is inserted into an opening, LL, opposite the second block, S^2. The screen, C, is put as near the block, S^2, as possible, but not so near as to allow any of the first diffused rays, or primary diffusion to reach it. It is imperative that the observer's eyes be kept in the dark for some time prior to work of the kind, and even the light of the Crookes tube itself should be carefully shaded from them. It was only after taking these precautions that the writer was able to obtain any decided effect, but then the result was unmistakable.

Other substances not so diffusive for the rays as paraffine is, gave no definite result, though it is thought that with further experience they will be found to act as does the paraffine, but more feebly. The writer has in mind several ways of multiplying the effect, but has not yet been able to carry them into practice.

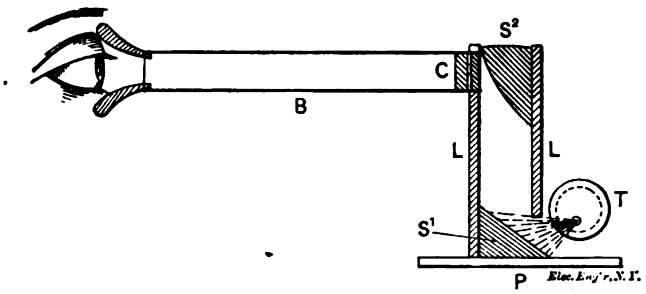

FIG. 2.

It may be mentioned here that the question of the different wave lengths of Röntgen rays would have considerable light thrown upon it, should there be found selective absorption or diffusion according to the substance used. By changing the substance of S^1 with relation to that of S^2, in Fig. 2, interesting relations might be found.

Since paraffine and many other substances diffuse Röntgen rays, while calcium tungstate does not, but gives out light instead, may it not be possible that there exist substances which absorb Röntgen rays and give out wave lengths above the visible rays in pitch or ultra-violet rays; and may not the choice of the substance determine where, in the range of wave lengths, between the luminous and Röntgen orders, the diffused rays may be found. It is even conceivable, but not probable, that substances exist which might, when submitted to Röntgen radiation emit rays below the red.

MISCELLANEOUS

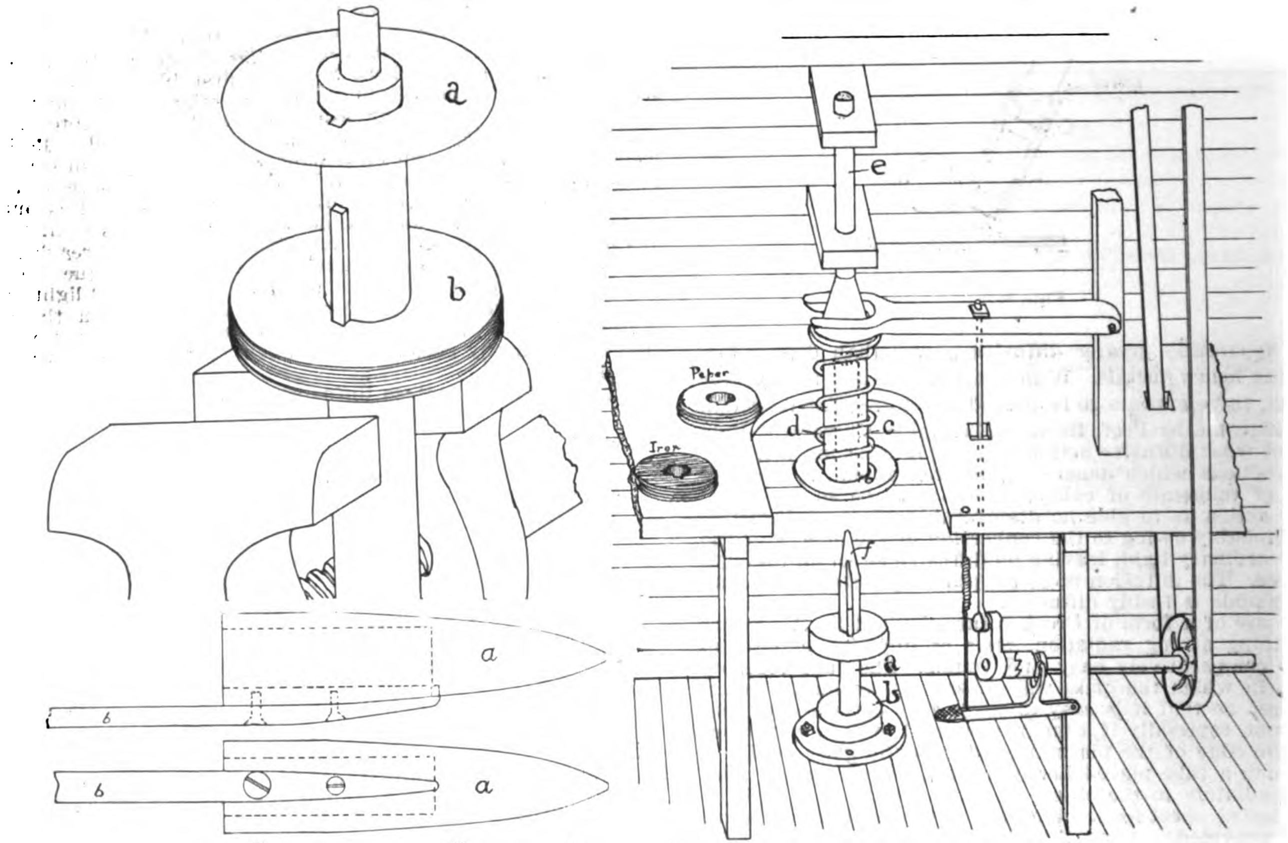
ELECTRICAL MACHINE SHOP PRACTICE.—I.

BY JAMES F. HOBART, M. E.

THE machinist has had so many new forms of material forced upon him during the past decade, and so many new designs, both mechanically and electrically, that he is entitled to the broadest possible exchange of ideas, especially through the media of his favorite journals. Only by exchanging and profiting by ideas have the machinist and the electrician been able to make the tremendous advance placed to their credit.

It is the writer's intention, in this series of articles, to give a description of general (and also special) shop practice as he finds it exemplified in the construction of electrical machinery. He also proposes to illustrate possible improvements in existing methods, as they appear to him, viewed from the standpoint of a mechanical engineer.

In motor and dynamo construction, too much importance cannot be given to the proper building up of the armature.



FIGS. 1, 2 AND 3.—HAND AND MACHINE METHOD OF STACKING ARMATURE DISCS.

Formerly it was considered the best practice to stamp out all the thin discs, one by one, in a press which also formed the channels for the winding. At the present writing, a number of concerns punch armature discs, some punching them all at once, by a single stroke, others punching them by the "step by step" method.

For the better class of armature work, it has been found that the forming of the wire grooves before setting up the armature, does not give the results that can be obtained by milling the armature slots after the discs have been all put in place, and the armature baked. The punching should be done with shearing dies on anything larger than 4 or 5 inches in diameter, and the hole for the shaft, and the key should be punched at the same time, a compound punch being used for the purpose. Discs less than 4 or 5 inches in diameter may be pressed out with a punch which strikes all around at the same instant.

The paper discs must also be punched, and the same dies that cut the iron, can be used for paper, but they must be kept very sharp or the thin paper will not be cut satisfactorily. One man should be given charge of all the dies and die work. He should have a good assistant, and no one else should be permitted to use, or even touch the dies, for it is very easy to spoil a $100 set of dies by a single cut if they are not properly set.

The making up of an armature as now usually practised, is a tedious operation, and should be improved at once. Fig. 1 shows about how it is managed in a majority of the shops. The armature shaft is caught vertically in a vise after one head has been put on, and a disc of paper put on over the top and worked down by hand, keeping the key-way so as to engage the slot cut in the disc for that purpose. It is a lot of work to do this, and consumes a lot of time.

It is desirable that a machine be worked out for putting on armature discs, both the iron and the paper. Something after the scheme shown by Fig. 2 might answer, the armature, a, being set into a stationary chuck, b, which is made fast to the floor, under a bench as shown. A hollow plunger, c, is fitted above the bench in suitable guides, so as to stand exactly over, and in line with the armature shaft as shown.

By a system of levers connecting with a crank shaft, the plunger, c, is made to travel vertically back and forth over the armature shaft, the collar disc at bottom of plunger fitting tight enough to the shaft to prevent any doubling of the paper discs under it. The spiral spring, d, serves to soften the pressure applied, also to allow the plunger to work when the shaft is nearly filled. Another spring, not shown in the engraving, but located at the top of the shaft, e, serves to raise the plunger to the position shown, whenever it is released by taking the foot from the treadle.

A cone, f, Fig. 2, is placed on top of the armature shaft, and serves as a guide to start the discs, both on to the armature shaft, and on to the key, or feather, as well. A detail view of the cone is shown by Fig. 3. The body of this jig is made of cast iron, or, preferably of brass. It is bored out to fit the end of the armature shaft, where the latter is shouldered down to receive the journal box. A number of bushings may be provided to fit the inside of cone, thus allowing it to be used on a number of shafts of the same diameter, but having differently shouldered ends.

The key, or feather, b, is fastened to the cone by means of a couple of screws and a turned-in pin at tip end of the key. This key is tapered both ways, as shown, so as to allow the discs to be easily revolved into position, with the slot fair with the feather. Then, the disc will follow down easily, to the feather on armature shaft, without danger of letting the discs get out of line with that feather, or of getting the paper crumpled up.

Referring again to Fig. 2, it will be seen that the discs are subjected to a considerable pressure every time a disc is put on. The result will be that the armature clamps together a good deal better than where it is put up by hand, and the discs are on much more even, making two points in favor of the machine, outside of the saving in time, which is very great.

By hand, in putting up 8-inch armatures, a good workman will put on a paper disc in about 15 seconds, and an iron disc in a little less time, making two discs of iron (with the intermediate paper) per minute. With the machine it will be very possible to start it to running about 60 revolutions per minute, letting it run continuously, and putting on a disc every time the plunger gets up out of the way, the discs being laid in piles, conveniently on the bench, as shown. The cone makes it very easy to arrange the discs so they will go down over the feather, thus making the machine put on 30 iron and 30 paper discs per minute, against two by hand. Surely nothing more needs be said in this direction.

The grooving of the armature for the reception of the winding should be done on a stiff milling machine, the dividing head being used in the same manner as for gear cutting. Where the number of armatures is large, and the sizes few, it will be economical to procure a special milling machine for this purpose alone, and have a double dividing head so arranged that two armatures may be milled at the same time, with very little more expense for setting and attending, than when one is milled at a time.

MAKING SODIUM PEROXIDE AT NIAGARA.

BY ORRIN E. DUNLAP.

THE Niagara Electro-Chemical Company have completed their electrical equipment, and the installation is one that is attracting some little attention. The company's buildings are of brick, and cover an acre of land; they number eight, besides the offices, and are devoted to transformer room purposes, pot room, etc. This plant was the fourth to start operations on the lands of the Niagara Falls Power Company.

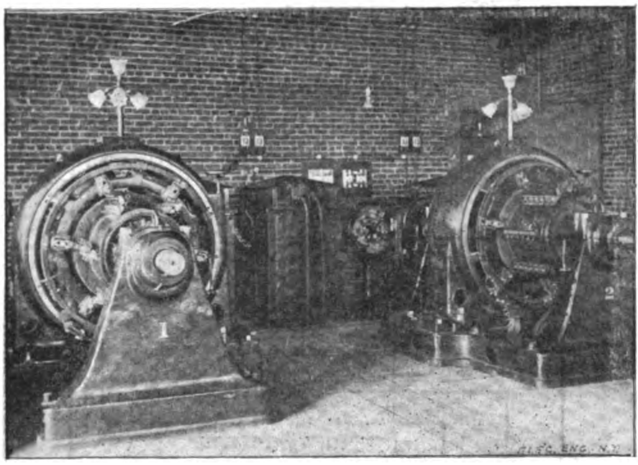


FIG. 1.

The electrical equipment consists of three 175 k. w. rotary transformers, which run at 500 revolutions per minute, and six static transformers which reduce the multiphase current of the Niagara Falls Power Company of 2,200 volts to 118 volts and arranged with Stillwell regulators, which still further reduce the voltage to 90 volts, as may be required. Rotaries Nos. 1 and 2 are shown in Fig. 1 and rotary No. 3 in Fig. 2. This last mentioned rotary is of the new induction type, and is the first ever installed commercially. The ordinary transformer has field coils which receive direct current from the rotary itself, but the field poles of this new type of machine derive their magnetism from the armature. No copper of any description is to be found around the field poles.

In addition to the above mentioned machines the transformer room contains a marble switchboard fitted with high potential plunger switches, instruments, dynamo changing switches, fuse plugs, field rheostats, circuit breakers, etc. The whole outfit was supplied by the Westinghouse Electric and Manufacturing Company, and installed under the supervision of Mr. W. K. Dunlap, the popular representative of the Westinghouse Company at Niagara.

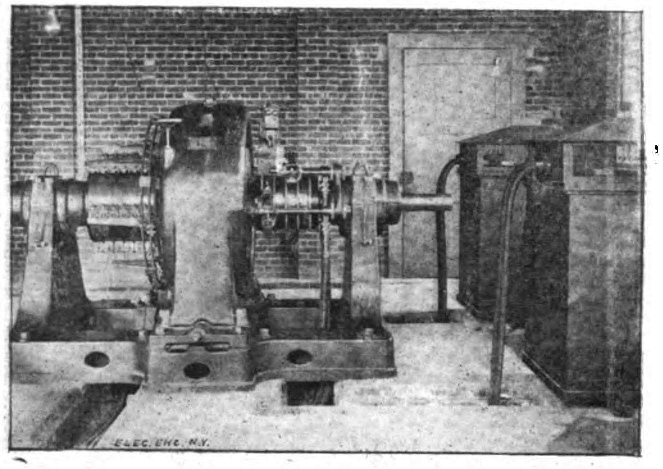

FIG. 2.

Copper leads run from the switchboard to the pot room, and current passes in series through the pots, which are filled with molten caustic soda. The sodium is bailed out of the pots regularly, and cast into bricks. There is a very conveniently arranged recovery plant for caustic soda, the pump for the liquors being driven by an induction motor.

Metallic sodium is converted into peroxide of sodium by a very interesting process. The sodium is put in regulated quantities into dishes which travel through a long tube fixed in a furnace. Dry air in regulated quantities is then passed through the tube, which is kept at a certain temperature, and the sodium is oxidized to peroxide. The peroxide comes out as a beautiful canary-colored substance, which is immediately sent to the grinding room to be ground and packed.

It will undoubtedly seem strange to some that a metal like sodium, which a few years ago was barely seen outside of the laboratory, should be made in such quantities, be handled with such ease, and be converted into a peroxide which gradually but surely seems to be taking the place of barium peroxide. Both are used in the manufacture of hydrogen peroxide solution. Until recently the bleacher has been obliged to buy his peroxide of hydrogen in the form of a solution, which is bulky and likely to lose its strength, and it is difficult to keep a bath of uniform strength. In peroxide of sodium, however, the bleacher has a substance which, it is said, contains twelve times as much oxygen available for bleaching as the ordinary ten-volume hydrogen peroxide solution, and which can be kept an indefinite time.

The plant of the Niagara Electro-Chemical Company employs about fifty men, who are divided into two shifts, as the process is continuous. The laboratory is well equipped, and Manager Brindley finds in it especial reason to be proud. Max Friedrichs is in charge of the company's office at the Falls.

STORAGE BATTERY ENGINEERING PRACTICE.—XIV.

BY JOSEPH APPLETON. (Copyright, 1897.)

The engravings Figs. 56, 57 and 58 illustrate the Bowling Green battery and apparatus. This is the latest of the three battery plants operated by the New York Edison Company and is equipped with the most modern devices and arrangements. The plant consists of 150 cells arranged 75 on each side of the three-wire system. Each cell consists of 33 plates mounted in a lead-lined wooden tank of the following dimensions: 40¾ inches high, 30½ inches long and 20½ inches wide. The cells rest on special double petticoat porcelain insulators to insure good insulation. The adjacent cells are connected together by lead bus bars to which the individual plates are welded in the manner previously described.

There are 20 regulating cells at each end of the battery

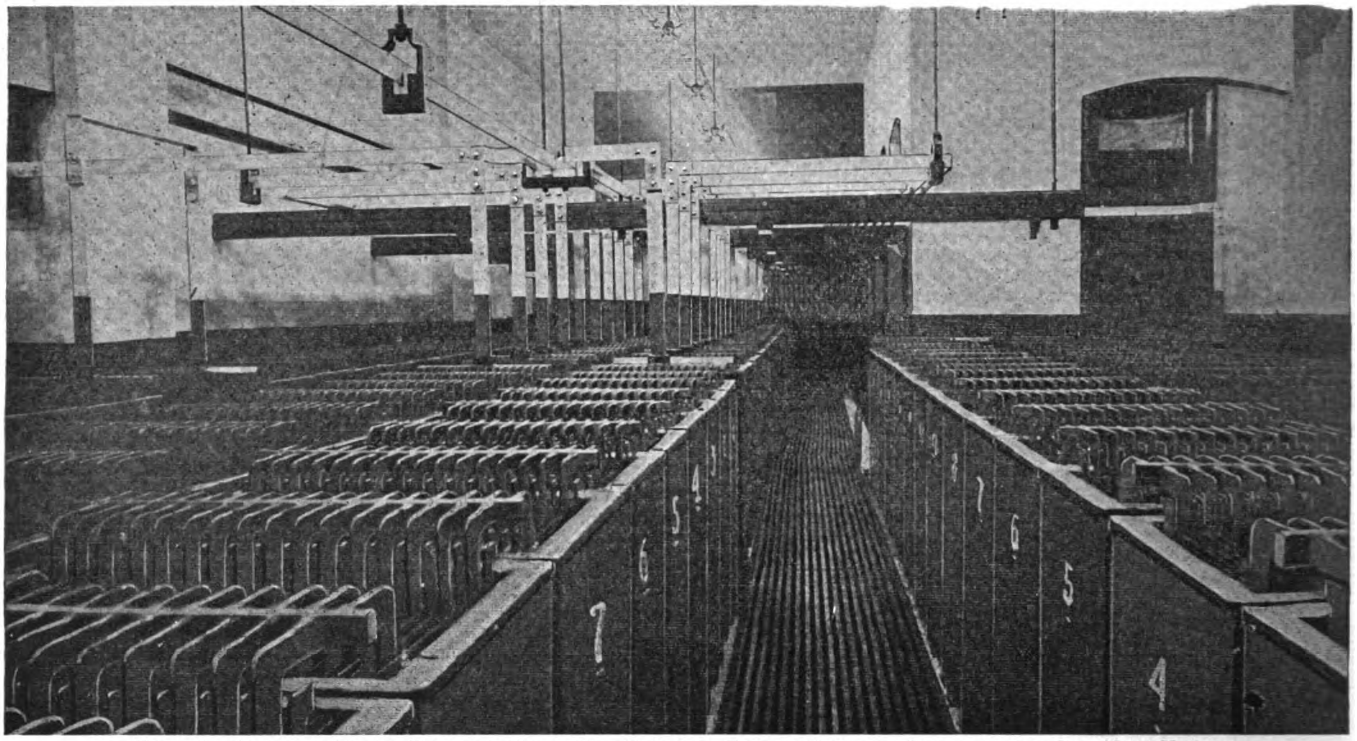

Fig. 56.—Battery Room, Bowling Green Sub-Station, Edison Electric Illuminating Co., New York.

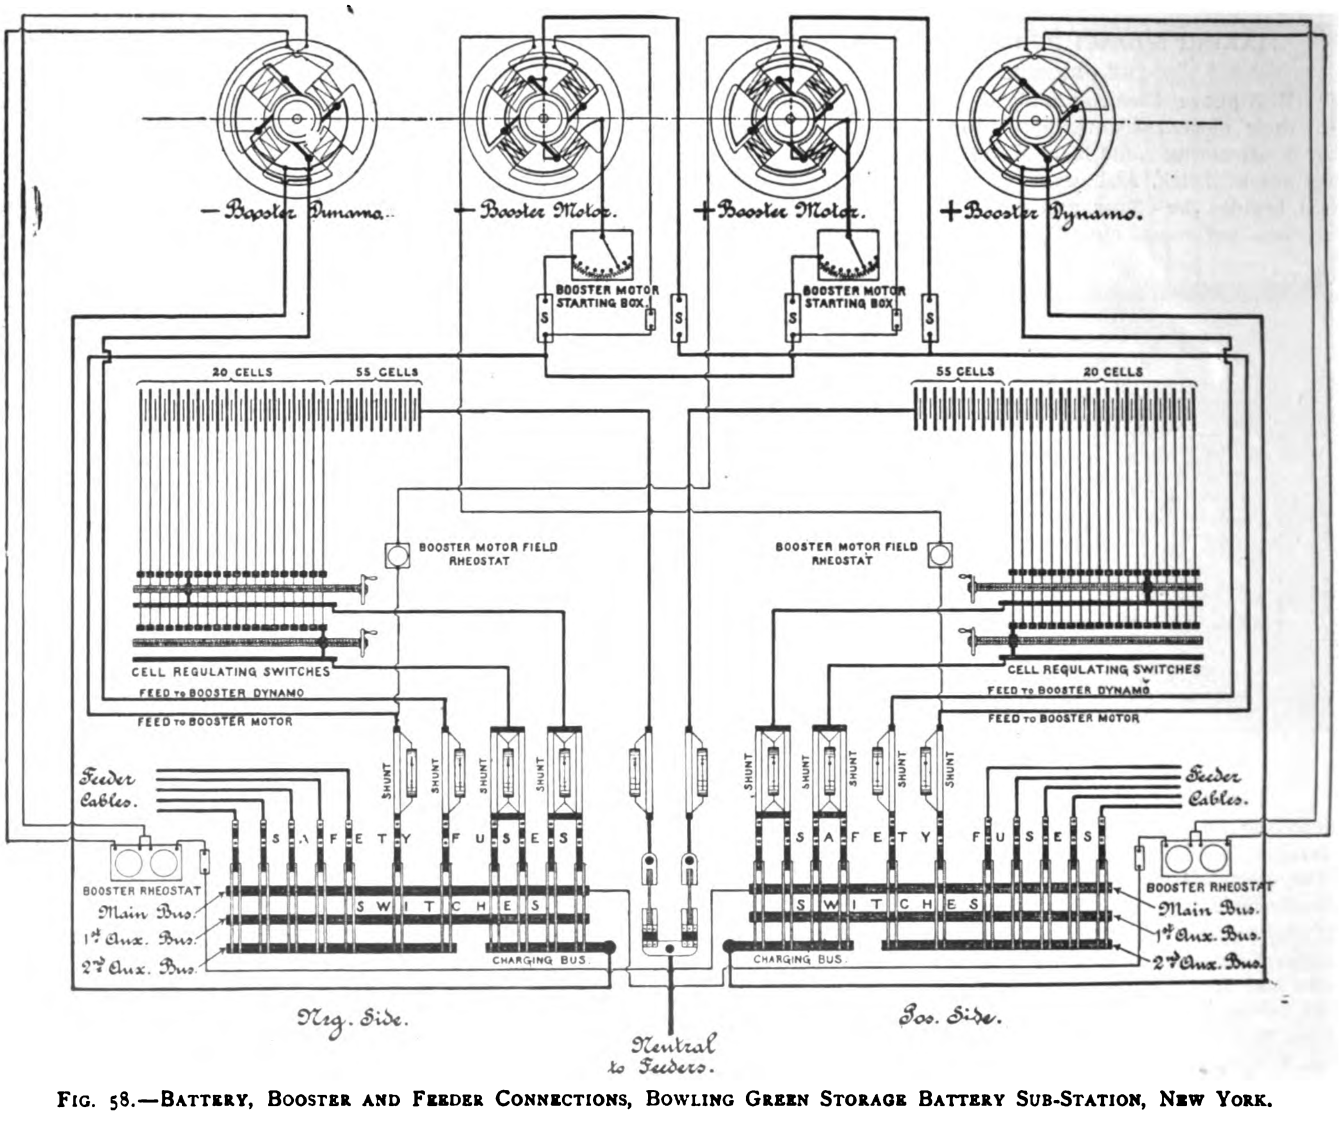

Fig. 58.—Battery, Booster and Feeder Connections, Bowling Green Storage Battery Sub-Station, New York.

which are connected to the regulating switches, the connections being made by means of copper bars 3 x 1½ inches supported on porcelain insulators. Two of these regulating switches are provided on each side of the system so that the battery may be discharged at two potentials or be charged and discharged at the same time.

The battery is charged by means of boosters which raise the bus pressure sufficiently to give the required voltage. These boosters are shown in Fig. 58. They have a capacity of 1,200 amperes and 60 volts, and are driven by compound-wound motors so placed that one or both motors may be used for driving the two boosters according to the load.

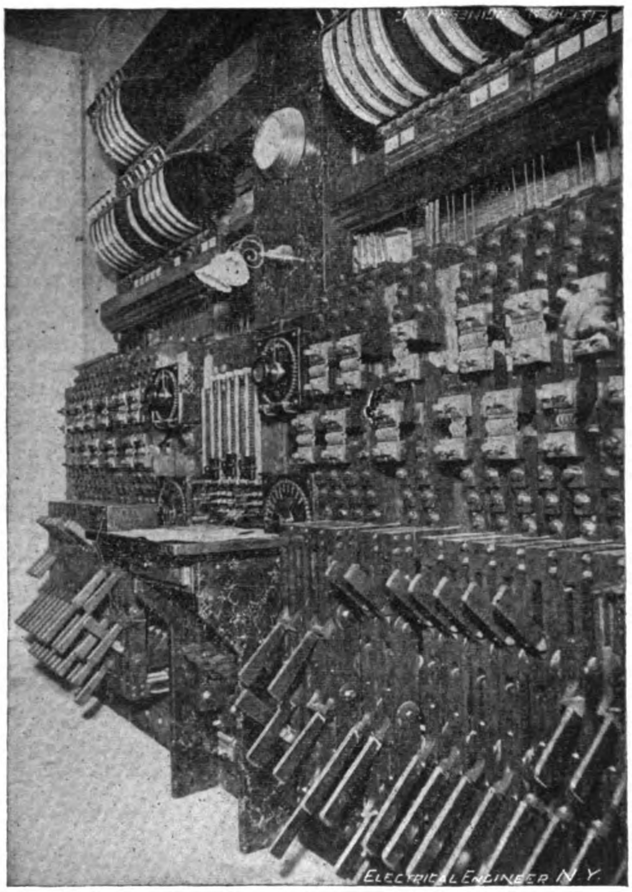

FIG. 57.—SWITCHING AND INDICATING APPARATUS, BOWLING GREEN SUB-STATION, NEW YORK.

Fig. 58 shows the connections and general arrangement of this plant, and Fig. 57 illustrates the switching apparatus.

THE INDUCTION FACTOR, A NEW BASIS OF DYNAMO CALCULATION AND CLASSIFICATION.[1]—II.

(Concluded.)

BY PROFESSOR CHAS. A. CARUS-WILSON.

SECTION V.

When the tractive effort, the speed, the tension of the line and the resistance of the motor are given, we can write

$$\frac{M\ v}{d} = \frac{E}{11.2\ S}\left\{1+\sqrt{\left(1-\frac{8\ R\ T\ S}{E^2}\right)}\right\} \qquad (11)$$

In designing a motor equipment to fulfill certain conditions, we must be able to distinguish between the part played by each of the quantities, M, v and d, in obtaining the desired result.

Example 10. A train and locomotive on the Baltimore & Ohio Railroad weigh 780 tons, and have to mount a grade of 0.8 per cent. at 10.7 miles per hour. The frictional resistance of the track is nine pounds per ton, reckoning at this rate both train and locomotive. The tension of the line is 625 volts. Four gearless motors are used, permanently connected in series, each having an internal resistance of 0.0209 ohm.

Each motor thus has to move 195 tons on a tension of 156.2 volts. The draw-bar pull per motor for the grade is 3,490 pounds; for friction, 1,755 pounds; allowing ninety-five per cent. mechanical efficiency, we get 5,500 pounds as the required tractive effort per motor; inserting this value together with those for E, R and S, in Equation 11, we find the value of $\frac{M}{d}$ to be 2.32, v being unity.

It appears then that whatever size of driving wheel we employ, the induction factor must be 2.32 times the diameter; and that so long as this ratio is maintained, the locomotive will haul the train up the grade at the required rate. For instance, if we take wheels 4 feet in diameter, the induction factor must be 111. If d is 5 feet 6 inches, M must be 153. The current at full speed is 850 amperes from Equation 8, and is unaltered by increasing or decreasing the ratio of M to d, so that we should take d as small as possible, consistent with leaving a clearance for the motor and its attachments. The actual values of M and d for the motors in use on the Baltimore line are M = 144, d = 62 inches.

When running at full speed each of these motors would be doing work at the rate of 158 horse-power, so that the horse-power of the locomotive would be 632. The current from the line would be 850 amperes, as obtained from Equation 8. This current will, not, however, start the train on the grade. We have to find then how much current is required to do this.

If the start is to be effected in forty seconds, since the final speed is 10.7 miles an hour, or 15.7 feet per second, the acceleration must be 0.393 foot per second. Inserting this value in Equation 10, remembering that W is 195, and $\frac{M}{d}$ is 2.32, we find the current required for acceleration to be 810 amperes, making a total current at the start of 1,660 amperes, or a force factor of 239 kilodynes. This agrees with the results obtained in starting a train of the given weight under the given conditions. (See Mr. Lee H. Parker's paper on the "Electric Locomotives Used on the Baltimore Line," published in the "Street Railway Journal" for March, 1896.)

USE OF THE INDUCTION FACTOR IN DYNAMO CLASSIFICATION.

SECTION VI.

Example 11.—Two generators run at the same speed and have the same kilowatt output. A is a generator giving ninety-six amperes at 125 volts, while B gives 9.6 amperes at 1,250 volts. These two dynamos differ radically, but the difference is one that their classification by kilowatt output fails to recognize. They differ dynamically, as can be seen by passing the same current through both, when the one machine will give ten times the torque of the other. This experiment can be made when the machines are standing still, so that the difference does not depend upon that of their induced volts when they are both running at the same speed, but, rather, the difference of volts depends upon the dynamical difference that exists whether they are standing still or whether they are running.

The induction factors of these machines can be found thus:

The low-tension machine has 200 conductors on the armature and 2.5×10^6 lines per pole, p being unity, so we have

$$M = 200 \times 2.5 \times 10^6 \times 10^{-8} = 5$$

The high-tension machine has 3,760 conductors and 1.33×10^6 lines per pole, p being unity, so that the induction factor is given by

$$M = 3,760 \times 1.33 \times 10^6 \times 10^{-8} = 50$$

A comparison of the induction factors indicates the real difference between these two machines. If they are to run as generators at equal speeds and give the same kilowatt output, the current delivered by one will be ten times that delivered by the other. If they are to run as motors at the same speed with the same horse-power output, one must run on a line tension ten times that of the other.

Example 12.—The motors in use on the Liverpool Overhead Railway and on the City and South London Railway are rated at about the same horse-power, but on actual test the Liverpool motor can pull over two of the South London motors when equal current is passing in all three.

The motors on the Liverpool Railway were designed to run in parallel, two motors to each car, while those on the South London Railway were designed to run permanently in series, two motors also to each car.

If the tension of the line, the speed and the drawbar pull were the same in the two cases, the induction factor of the Liverpool motors must be twice that of the South London motors: the values were actually 120 and 60 for 100 amperes in the series winding in each case, the force factor being twelve and six kilodynes, respectively, for this current. Hence, each of the Liverpool motors must give twice the drawbar pull of one of the South London motors for the same current, provided the wheel diameter is the same in both cases. The wheels on the Liverpool cars have a diameter of 33 inches, while those on the South London cars are 27 inches diameter; so that the respective drawbar pulls for 100 amperes would be (taking the values of M as given above), for the South London motors, 630 pounds, and for the Liverpool motors, 1,030 pounds.

---

[1] Read before the N. E. L. A.

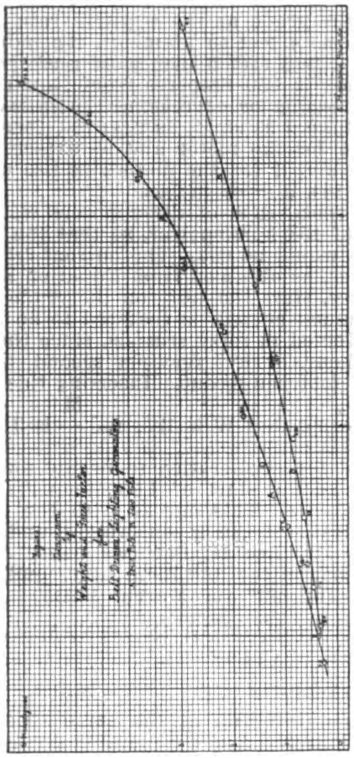

FIG. 1.

We must not infer from what has been said that the Liverpool equipment is necessarily more efficient than the South London equipment when running at full speed, because, although for equal speed and drawbar pull the current per motor in the former would be half that in the latter, yet since the South London motors are in series, the current from the line is the same.

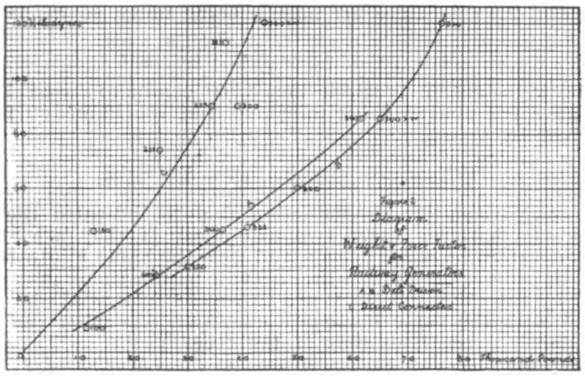

FIG 2.

SECTION VII.

If we take the weights and the force factors of a number of dynamos belonging to the same type and plot them on rectangular axes, we obtain a series of points lying on a curve.

In Fig. 1 this curve[1] has been plotted for two types of dynamos manufactured by the General Electric Company; Type A is a four-pole and Type B a two-pole, belt-driven lighting generator. The vertical ordinates give the force factor in kilodynes, and the horizontal ordinates give the weights in pounds.

The curves afford a convenient way of comparing the two types. The well known fact that the four-pole machines give a greater output for equal weight than the two-pole machines is clearly shown. The numbers against each point show the rated kilowatt output. All the dynamos in this diagram are wound for 125 volts. Equal force factors and equal speeds give equal kilowatt output.

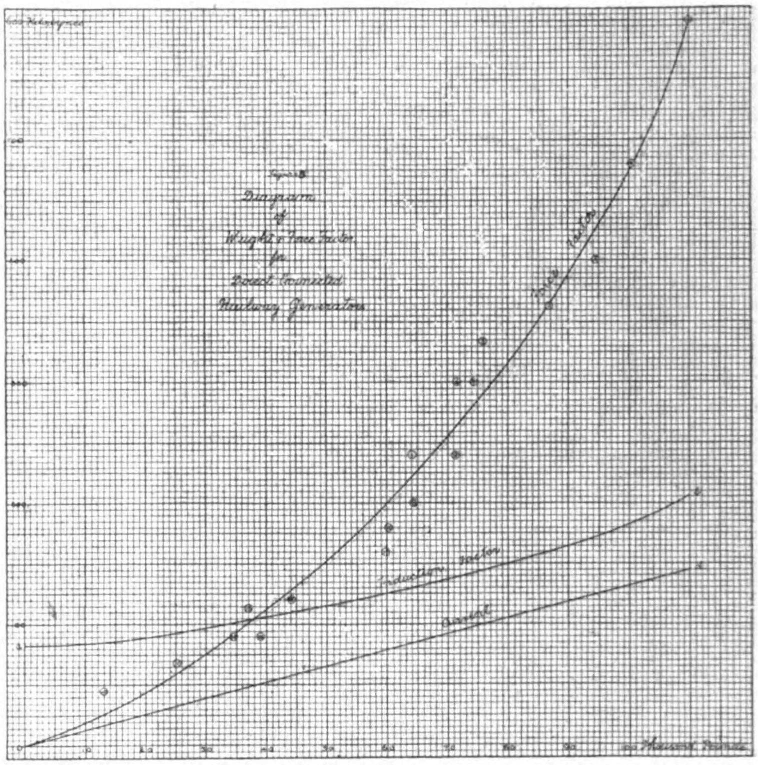

FIG. 3.

The force factor corresponding to any weight may be made up in a great number of different ways, by taking different values of M and C.

For instance, taking a force factor of 2 kilodynes, we may have machines of equal weight with the following differences:

C.	M	MC	Revolutions per minute for 125 volts.	Kilowatts
200	10	2,000	750	25
250	8	2,000	940	31
340	5.9	2,000	1,270	42
400	5	2,000	1,500	50

There is thus a considerable range of output for a machine of given weight, according to the speed at which it is to run. For this reason we may find machines of the same type giving equal output, but of different weights, the heavier machine running slower than it need do, if it occupied its normal position on the force curve.

Thus a dynamo of this type, giving 340 amperes at 125 volts at 1,270, will weigh 3,550 pounds, and have a force factor of two kilodynes. A dynamo of the same type, weighing 4,750 pounds, has a force factor of three, and, if required to give 340 amperes at 125 volts, must have an induction factor of 8.83 and run at 850.

Fig. 2 gives the curves of force factor and weight for different types of railway generators. A and C are made by the General Electric Company, the former belt-driven, the latter direct-connected. B is made by the Walker Company, and is belt-driven; the numbers opposite to each machine indicate the rated kilowatt output, all at 550 volts.

Fig. 3 gives the force factor curve for the complete line of direct-connected railway generators made by the General Electric Company. The particulars of the machines are given in the table. All these dynamos are wound for 550 volts.

---

[1] The form of this curve was first noticed by Mr. E. Wilson, in a paper recently read before the Institution of Electrical Engineers in London; the force factor is there spoken of as the mass factor.

The vertical ordinates of the force curve represent the product of the induction factor M and the current C. If both these quantities increased uniformly with the weight, the force curve would be a straight line. The bending up of the curve indicates that either or both of these quantities does not increase uniformly with the weight.

If we plot the induction factors corresponding to each machine as vertical ordinates, the points thus obtained should lie on or above a curve giving the smallest induction factor for a machine of any weight; i. e., indicating the highest speed at which a machine of that weight may be run. The points may lie above this curve, since a dynamo of any weight can be run at a speed lower than the limiting speed, but the points should not lie below this curve. By dividing the force factor for any weight by the corresponding induction factor, we obtain a third curve which gives the variation of the current with the weight.

In Fig. 3 the curve a b has been drawn on the assumption that the current curve o d is a straight line. It is probable that it is not quite straight, but it would seem that the weight varies very nearly as the current. The induction factors are plotted vertically on a scale of one inch equal to one hundred of M, and the currents on a scale of one inch equal to 500 amperes.

As an illustration of the use of the curve, let us find the lightest dynamo of this type that will give 500 kilowatts at 550 volts.

Poles.	No. in Diagram.	Rated kilo watt output	C.	R.P.M.	M.	M. C. kilod.	Weight 1,000 lbs.
10A.	1	500	910	125	264	240	64.0
10B.	2	. .	....	75	440	364	87.1
10B.	3	...	....	90	367	334	76.0
10B.	4	..	....	100	330	300	71.3
10B.	0	800	1,450	80	412	600	110.0
10B.	5	...	....	120	275	400	94.4
10C.	6	...	...	100	330	480	100.9
8A.	7	400	725	80	412	300	74.2
8A.	8	...	....	120	275	200	64.3
8A.	9	...	. .	100	330	240	71.4
6A.	10	150	270	200	165	44.5	13.1
6A.	11	225	410	200	165	67.5	25.1
6A.	12	...	....	150	220	90.0	34.3
6A.	13	...	..	120	275	113	37.0
6A.	14	300	545	200	165	90.0	39.1
6A.	15	...	...	150	220	120	43.9
6A.	16	...	....	100	330	180	60.4
6B.	17	400	725	150	220	160	59.7

The current is 910 amperes, and the weight, consequently, 69,000 pounds. The corresponding induction factor is 270, so that the machine must run at 122 revolutions per minute.

If we look at the list of dynamos in the table, we shall see that the lightest dynamo of this output, actually made, weighs 64,000 pounds, and runs at 125 revolutions per minute, being thus a little lighter than that indicated by the theory.

Note.—The limits of this paper do not permit me to insert the proofs of the equations it contains. These will, however, be found in full in the work on Electro-Dynamics, which I am now preparing, and which will shortly be published by Messrs. Longmans, Green & Co., London and New York.

AN ELECTRICAL EXHIBITION FOR RUSSIA.

W. Toritch & Co., of New York City, have been advised that an electrical exhibition is being planned by the Russian Electro-Technical Society to take place in St. Petersburg the early part of 1899. Everything pertaining to electricity will be admitted. This will give an opportunity to introduce in Russia, they say, a number of American manufactured goods in the electrical line which heretofore were unknown in that market. The exhibition buildings will be put up in the center of the city. In the surrounding canals electric yachts will ply. Different systems of electric railroads, suspended as well as on sleepers, will be built, and also electric elevators and moving platforms. Some of the buildings put up at Nijni Novgorod for exhibition purposes will be taken to St. Petersburg. At the close of the exhibition some of the principal exhibits will be retained to form an electrical museum in St. Petersburg. Several millions of roubles, which will be necessary for the expenses of the exhibition, will be furnished by the Russian Government, the city of St. Petersburg, and by the Electro-Technical Society of that city.

RECENT PROGRESS IN ARC LIGHTING.[1]—II.

BY PROF. ELIHU THOMSON.

There are two ways in which alternating currents may be used to work arc lights in series. We may either take a constant-potential system, such as one with main lines at 1,000 volts and connect between them a series of arc lamps at about thirty volts each and about thirty-five lamps, or we may transform so as to feed the lamps in series with a current of constant value, or with a current which does not vary more than a given per cent, from light to full load—15 per cent., for example. In the former arrangement some provision must be made to allow lamps to be extinguished without breaking the circuit, and this cannot be done by shunting, unless equivalent-resistances be substituted, for the shunting of a lamp or lamps in a series would result at once in a great increase of current in the others and a serious departure from normal working.

By shunting each lamp in the series by a specially constructed and carefully proportioned reactive coil, wound upon a laminated core, the difficulty just pointed out is obviated with but small sacrifice. Another way of accomplishing even a better result, but one which requires that shunt or differential magnets be used in regulating the feeding of the carbons, is to substitute, by a special switch, a proper reactance in place of the lamp when it is to be cut out, and also to cause the lamp, on a failure to feed, to cut in as a substitute for itself this reactance.

When a transformer is so constructed that there may be a considerable magnetic leakage, as it is termed, between the primary and secondary coils, it approximates what is called a constant-current transformer. It will, if connected by its primary terminals across mains at constant potential, give a secondary current which, even at short-circuit, is only a moderate percentage in excess of that given when the secondary is carrying a considerable load. In fact, such a transformer has an analogy, which is unmistakable, to a direct-current arc machine with a drooping characteristic, before alluded to.

For arc lamps in series on alternating current, this constant-current property is perfectly adapted. But in this case the regulation of the lamp must be by a shunt magnet responding to the potential across the arc, and not to the current passing through it, which is constant. The inclosed arc lamp, broadly speaking, is an outcome of the ability to secure very nearly pure carbons, or carbons containing little or no ash and particularly free from such metals as iron, the oxides of which are deep black or brown, which would soon obscure the small globe around the arc.

When it is remembered that, to get the best results with arc lamps on constant-potential circuits, the use of rather expensive cored carbons is necessary, the saving of carbon and frequent trimming becomes a very important item and permits the employment of more expensive carbons, provided they last long enough. The high voltage demanded by the inclosed arc was soon seen to be not a disadvantage, but a positive advantage for constant-potential circuits, inasmuch as it permitted the use in one lamp of a larger fraction of the total—generally 110 volts. Hence, instead of keeping down the potential, it could even be raised from sixty-five to seventy-five or to eighty volts with advantage. In fact, it may be that the exclusion of oxygen has the effect of enriching the arc flame itself, in much the same way that a slightly luminous blue flame of a Bunsen burner becomes far more luminous by cutting off the air. There may, in fact, be free condensed carbon particles in the outer layers of the arc stream highly heated and, therefore, strongly luminous. The flat ends of the carbons tend, also, to cause the hot gases to be retained under the positive end, thus extending the heat of the crater and increasing the luminosity. The result of the almost complete exclusion of oxygen is that very little combustion takes place and the life of the carbon is therefore much extended. The function of the small glass vessel around the arc is not only to keep out the air, but, in addition, to act as a diffuser of the light evolved, and in this sense replace, to a considerable extent, an opal outer globe of large dimensions, necessarily thick and highly absorptive. The inner globe around the arc is made thin, to withstand heat without cracking from sudden changes of temperature, and is generally of clear glass with a thin coating, either internal or external, of an opal or alabaster-like glass, which, by the materials employed in its composition, gives a large diffusive effect without undue absorption. The inner globe is often also given a yellowish color or absorptive effect for the disagreeable violet rays, of which the long arc flame is so strong a source.

---

[1] Read before the N. E. L. A. Abstract.

Owing to the traverse from side to side of the arc between the square ended carbons, the direction in which light is emitted from the arc most effectively is undergoing continual and very great changes, so that the intensity of light in any given direction may, in a few seconds, vary several hundred per cent., and with a perfectly clear glass inclosing globe this variation would not only be quite noticeable, but in many cases intolerable. The diffusive power of the glass, however, is such, in the case of the opal coating, that the traveling of the arc is, in large measure, compensated, and the general effect is that of a very steady, uniform light. Were it not for the diffusive power, the color of light, as well as the intensity, would change greatly; as when the arc happened to be on the side of the carbons away from the observer, the light would then be in greater proportion from the purple or violet arc flame, and less from the glowing ends of the carbons themselves.

The carbons to be used in an "inclosed arc" should be of the very highest grade as to purity, not too hard or dense, as straight as possible, uniform in diameter and circular in section, and should be obtained of as near a standard diameter as possible, so as to avoid the necessity for adjusting the caps of the inner globes to the size of the carbons. It is necessary that the caps should fit pretty closely around the carbons to avoid leak and consequent reduction of life. Leaks of air into the inner globe must be carefully avoided, if any reliance is to be placed upon a lamp for a given run without recarboning.

The mechanism of an inclosed arc lamp to be run singly in branches from 100-volt circuits is naturally very simple. Since the lamp regulates entirely by variations of current on its circuit, a simple series magnet suffices. No cut-out other than a fuse in the lamp branch is needed. In the use of "inclosed arcs" instead of "open arcs," one does not escape from the necessity of using in the branch with the lamp a choking resistance.

For the purpose of discovering the minimum drop of potential required to exist over a dead resistance in circuit with arcs on constant-potential mains, the writer instituted and had tabulated a series of tests in which the resistance in circuit with arc lamps was gradually cut down along with the line voltage, while the current and voltage of the arcs were maintained the same. A set of tests was made with two Thomson '93 lamps in series, using at one time plain National carbons, and at another a cored upper of one-half inch diameter, and solid lower carbon of one-half inch diameter. Also a set of tests was carried out with eighty-volt inclosed arc lamps adjusted for currents of different amount at different times. During each test the line voltage was lowered and resistance cut out until instability of arc and current resulted, while up to that time the current and voltage of the arc were kept the same during the particular test.

The general result of these tests was as follows:

Two '93 Arc Lamps in Series, with Variable Resistance.—One-half inch National Carbons: With 45 volts at each arc and a current of 9.6 amperes in the lamp branch, line voltage could not be reduced below 110 volts. This would give a drop of 20 volts over resistance and lamp magnets; with 45 volts at arcs and 7.9 amperes, the limit was reached at 108 volts on the line; with 46 volts at arcs and 6 amperes, the limit was 108 volts on the line.

Two '93 Arc Lamps in Series, with Variable Resistance.—Carbons, ½ inch cored upper; ½ inch solid lower. With 46 volts at arcs and 15 amperes current, the limit was 106 volts on line; with 46 volts and 12 amperes, the limit was 104 volts on line; with 46 volts and 9.4 amperes, the limit was 108 volts on line; with 45 volts and 7.3 amperes, the limit was 104 volts on line; with 42 volts at arcs and 6 amperes, the limit was 98 volts on line.

Test of 80-Volt Inclosed Arc Lamp, with Variable Resistance in Its Circuit.—Solid upper and lower 7-16-inch "Electra" carbons: With 75 volts at arc and 7 amperes, the limit of line voltage was 88 to 90; with 74 volts at arc and 6 amperes, the limit of line voltage was 92 to 94; with 75 to 76 volts at arc and 5 amperes, the limit of line voltage was 92 to 94; with 78 volts and 4 amperes, the limit of line voltage was 98 to 100; with 76 volts and 3.2 amperes, the limit of line voltage was 100. (Carbons, ⅝-inch "Electra.")

The above tests are, doubtless, sufficiently accurate to show the main point very clearly. This is that a certain line voltage as a minimum is absolutely necessary in working arc lamps on constant-potential lines, whether they be open arcs or inclosed arcs. Thus, two 45-volt arcs in series, with uncored carbons like the brand known as "National," cannot be safely worked below 110 volts on the line with resistance in series with them. More than 110 volts should, of course, be maintained for safety of the service. The tests show, also, that, with a cored upper carbon, the limit is lowered several volts on the average, and it is known that the voltage of the arcs may be safely reduced somewhat when cored positives are used.

It is also shown that a 75 to 80-volt arc, run upon a constant-potential line, is stable at considerably less line voltage than the open arc. It would appear, also, that, with either open or inclosed arcs at ordinary current strengths of from five to ten amperes, the steadying resistance in the branch is required to cause a drop of about 15 to 20 volts, or waste energy at the rate in watts of fifteen to twenty multiplied by the amperes of current used in the lamp.

What the development of the art would have been if the voltage of our incandescent circuits was, as originally set, say, 90 volts, instead of 115, is a subject for meditation.

The running of single alternating-current arc lamps on constant-potential circuits is facilitated by the ease with which, by a transformer or compensator, the potential required for the lamp may be obtained.

An alternating arc is peculiar, and different from the continuous-current arc in a number of important particulars. The fact that the arc is extinguished between successive alternations at the zero points of the current wave, and at a rate equal to double the periodicity, results in the musical sound of the arc, which may become a source of annoyance. The same cause gives rise to difficulty in starting the arcs without having them chatter, for until the carbons get strongly heated the arc is not re-established after extinguishment with the carbons separated. With cold carbons, the carbons must touch each other after an extinguishment at the zeros. Hence, the carbons must be separated very slowly, while a large current flows so as to strongly heat their ends, or a higher potential than that to be used in running the lamp after starting must be applied at first. Another way is to employ a resistance, or, better, a reactive coil in circuit with the arc lamp, so as to change the character of the potential at the lamp terminals, which then becomes less than that of a constant potential, and, in fact, begins to approach, in a measure, constant-current supply. But in the use of a resistance or reactance in circuit with the lamp, it is, of course, necessary to increase the potential of the line accordingly, so as to give the proper potential to the arc; while both expedients involve a loss of energy. It is found not to be practicable to run alternating arc lamps on circuits much below forty cycles; the common rates of sixty and 125 are well adapted to the case.

The efficiency of the alternating arc as a source of light has been shown by Prof. A. E. Blondel, in a recent paper, to be quite variable. It depends on the length of arc used with the particular carbons employed, and on the diameter of the carbons, as with continuous current. It also depends on the form of the wave of the alternating current. It was found that, with a rectangular wave alternating current, such as may be produced by reversing a continuous current by a commutator, the light given out was as seventy-nine to fifty-nine in the case of sine wave currents. This should follow from the fact that the extinctions, as Blondel pointed out, were instantaneous in the first case, and lasted for about one-quarter of an alternation in the case of the sine wave.

The writer takes occasion to express the opinion that, with very flat-topped waves, or waves approaching closely to rectangular waves, the limit of periodicity would be found far below forty per second, as regards the maintenance of an arc. If the reversal or passage through zero is quick enough, almost any reduction of periodicity would become possible. There are, however, practical considerations which set the limits in such a case.

Soft carbons, or those best suited to readily furnish considerable volatile matter, seem to be best adapted to alternating-current arcs, and they are frequently cored. The color of the light suffers some in consequence.

THE AMERICAN LIGHTING COMPANY FOR BANGKOK, SIAM.

One of the most important and probably remunerative concessions that has been granted in Siam for some time past was signed on Saturday night by the minister of finance, says the Siam "Free Press." The concession in question grants to Mr. L. E. Bennett, an American engineer, the exclusive right to work the concern known as the Siam Electric Light for a period of ten years, with the option of holding the concession and all exclusive rights for an additional ten years, at Mr. Bennett's pleasure. The terms of the contract give Mr. Bennett the exclusive right to light Bangkok and suburbs.

The palace authorities guarantee to patronize the lights and to take double the candle-power now in use for the palace, public departments and streets. At the present time the estimated quantity in use is 30,000 candle-power, which the Siamese will increase to 64,000.

For the above purposes a local company has been formed with a capital of 100,000 ticals, to make necessary repairs and alterations, and increase the efficiency of the concern. This sum was promptly taken up in a few hours on Saturday night by a few local business people, and, judging by the eagerness to obtain shares of 1,000 ticals each, ten times that sum might have readily been covered locally. There is not a business house in Bangkok that will not patronize the new venture, and we may safely assume that a great and rapid development will take place in Bangkok in the manner of lighting public offices, streets and private residences with electricity. For all concerned, the concession is a sensible departure, and one which will prove as advantageous to the Siamese treasury as to the concessionaire and those persons fortunate enough to have obtained interests in the company.

THE WELSBACH INCANDESCENT GAS LIGHT FOR UTILITY AND ECONOMY IN STREET LIGHTING.[1]

BY H. WILKIEMEYER.

On the thoroughfares of great cities, where the business blocks and factories stand on the inner edge of the pavement, there can be no more powerful agent in turning night into day, brilliant as when the sun hangs high in the heavens, than the electric arc. The vigilant eye of the night watch can scan the entire length of street and alley and the thief and midnight prowler, the thug who seeks the dusty shades will, like Othello, find his occupation gone.

But go with me to the side streets of the village or the suburbs of the great city where the houses stand back from the street, the pride and glory thereof being the spacious and well-kept lawn, where the pavements are shaded with rows of trees that meet almost in the middle of the street and lend a sylvan beauty to the scene.

What is needed to make safe an avenue of this kind, the pride and glory of the place? Is it the arc electric light hung high in the air and throwing its light in the heavens? No, it is not calculated for such use.

There can certainly be no claim that the electric arc lamp is of any practical use in the residence portions of towns, cities or villages, where trees line the streets.

My personal experience is that the public is better pleased and receives better service from the use of the Welsbach than the arc electric. In my own city the Board of Public Works which had displaced the use of gas in 1882, in accordance with the law of the city charter prior to the expiration of the contract made in 1882 and 1885, and which expired in 1895, advertised for bids to supply 400 electric lamps of the nominal 2,000 candle-power. The Welsbach burners having proved satisfactory, the Board awarded us the contract, stipulating the placing of 250 arc lamps and an indefinite number of gas posts fitted with the Welsbach burner.

We now have in nightly operation somewhat more than 400 street gas lamps with Welsbach burners, and they are so universally popular that up to this time we have not yet erected the full complement of 250 arc lamps provided for in the contract, by a considerable number.

For this burner, the price received from the city is $20 per year, every night all night, or $1.66 per month for each gas post. The 2,000 candle-power electric arc lamp costs the city $95 per year, or about $8 per month, and does not give the police protection afforded by a very few Welsbach lamps.

January 1, 1896 we had 155 lamps in operation.

The following table shows the cost of renewals:

	Mantles.	Chimneys.
In January connected 105 posts, renewals required.	3	2
In February ....renewals required.	26	2
In March connected 56 posts, renewals required.	25	4
In April connected 2 posts, renewals required.	62	7
In May connected 11 posts, renewals required.	54	2
In June connected 12 posts, renewals required.	79	3
In July connected 9 posts, renewals required.	96	4
In August connected 2 posts, renewals required.	80	8
In September	80	7
In October	92	4
In November c'n'c't'd 26 posts, renewals required.	65	5
In December con'ct'd 2 posts, renewals required.	63	2
Tot. No. of lamps 380; renewals, all lamps in use.	724	50

The total cost of breakage and renewals during the twelve months of the year 1896 was only $276.75.

But what is being done in the way of improvement in outdoor lighting in the great cities of this and other countries? In Boston, New York, Baltimore, Buffalo, Providence, Richmond, Chicago and Philadelphia the electric light is being superseded by the Welsbach gas burners.

DISCUSSION.

Mr. Ferrier.—I find, especially in the South, that we have trouble with flies and bugs in the Welsbach burner.

Mr. Highlands.—It is hardly necessary to say that the article just read, with its inferences and deductions, is a somewhat surprising one to present to a body of gas engineers, men whose sole ambition is to make gas cheap, and sell plenty of it. In the first place, the gentleman states that, on the thoroughfares of cities which are lined with business blocks and factories, the arc light is undoubtedly the best for street illumination. What a position this is in which to put the poor gas man who has no electric light plant. He must surrender the streets where he has large mains and an unlimited supply of gas to the electric light company, and on the outskirts of town, where he has no mains, he must surrender it to the man who is furnishing gasoline lamps. Thus you have him between Scylla and Charybdis, and he is continually harrassed, on the one hand, by the electric light man for more territory, because forsooth there has been another factory or another business block built a little further out, and some parts of several streets either have very few trees, or those they have are little ones, and, as a consequence, from this gas man's standpoint, the electric arc is certainly the best. On the other extremity, the gasoline man insists in pushing his lights a little further into the territory, because he is furnishing a much cheaper light; but it is not from this standpoint I especially wish to draw your attention. I cannot see how the gentleman can justify himself to his company in recommending the use of the Welsbach lamp instead of the arc lamp, when he had the opportunity of furnishing either one. Let us see how it figures out. He says he has erected about 400 gas lamps with Welsbach burners, for which he is receiving $20 per year each. With an estimated consumption on those lamps of, say, 4 feet per hour, and running 4,000 hours per year (which is a fair average), we find he is furnishing, through his 400 lamps, 6,400,000 feet of gas, for which he is receiving $8,000 per year, or exactly $1.25 per 1,000. Now, suppose he had gone to my friend, Mr. Lloyd, and bought a gas engine to use for running a dynamo for supplying arc lights. The accepted rating of power for a 2,000-candle arc light is 1 indicated horse-power for each arc light, and any good gas engine will furnish 1 horse-power with 18 feet of gas per hour, which would mean 72,000 feet of gas per year for each arc lamp, on the same basis as we have already figured the Welsbach light. Now, on this basis, the 150 arc lamps that he has displaced would use 10,800,000 feet of gas per year, and at the price he names, of $95 per year, he would have received for this gas $14,250, or $1.31 per 1,000 feet. Now, if these deductions are correct, what has he done? He has deliberately thrown away a chance of selling 10,800,000 feet of gas to be used on his own premises for $1.31 per 1,000, and accepted one of selling 6,400,000 feet of gas, to be distributed all over the city, at $1.25 per 1,000 feet, and I question whether the attendance on the arc lamps would be any more expensive than it would be on the Welsbach street lamps.

Several members inquired as to methods for keeping out bugs, and the adoption of a screen was recommended as having proved efficacious.

As regards chimneys, Mr. Wilkiemeyer said he used mica chimneys, as they did not break so easily as glass. The experience at Windsor, Conn., had shown both glass and mica to be defective and now no chimney was used in that town. The breakage of mantles by jarring due to passing vehicles was also discussed and several remedies suggested.

Mr. Prendergast stated he had had experience with 2,000 Welsbach lamps during the year and pointed out the different requirements for an indoor and outdoor Welsbach lamp; also the precautions necessary and device to prevent explosions and shattering of the mantle when lighting the lamp. He employed a vibrator to take the jar of passing vehicles, and advocated the use of a chimney in order to get the best efficiency from a Bunsen burner.

Mr. Prendergast then read a communication to Mr. Martin Mahoney, president of the Welsbach Street Lighting Company, from Mr. C. C. Simpson, of the Consolidated Gas Lighting Company, of New York. In this letter Mr. Simpson details the several unsuccessful experiments tried with Welsbachs as far back as 1894, and to their final successful employment on the Boulevard, where there were now 304 double lights. Recently 157 Welsbachs had been ordered for lighting

---

[1] Abstract of a paper read before the Pacific Coast Gas Association.

Twenty-fourth and Twenty-sixth streets from Sixth avenue to the North River. A letter was also read from Mr. S. McCormick, Superintendent of Lamps, of New York, giving similar information regarding the use of Welsbachs in New York.

In response to Mr. Highland's criticisms Mr. Wilkiemeyer stated that he had to meet certain conditions. In his case the city wanted 400 lamps instead of 200, but did not want to spend any more money than it had done before.

MUNICIPAL GAS NOT A FAILURE.

BY W. C. DODGE.

As a reader of The Engineer I have noticed for a long time the various articles, editorial and otherwise, against the idea of municipal ownership of gas and electric lighting plants. If I ever get the time I propose to furnish some facts bearing on this subject, but just at present I want to say a few words in reply to an article in The Electrical Engineer of May 19, entitled "Municipal Gas a Sad Failure."

That article was based, as stated, upon a report of a committee of the Pennsylvania Legislature. It is stated that one of the witnesses estimated the loss to the city by its investment in its gas plant at "not less than $700,000 per annum;" that the cost of the labor in the works was about three times what it ought to be; the production of gas was but one-third of what it ought to be, and that the city does less than half its own lighting, buying part of its supply from a private company at 37 cents per 1,000 and so on.

It is a very easy matter for hired or interested experts to figure out for investigating committees almost any result that the committee, for political purposes, may desire, or that interested parties may require. We have had an illustration of that fact in a recent investigation of the gas company in Washington, D. C., by a Congressional committee, in which the most ridiculous and absurd statements were made; but of that hereafter.

Instead of the gas plant being a great loss to the city of Philadelphia, the official report for 1894 shows exactly the opposite. According to that report, from 1891 to 1894, inclusive, there was expended "for material, maintenance, labor, supplies, coal, etc., $10,858,910.58, and for extensions and permanent improvements, $1,050,248.81; a total of $11,909,159.39. During those four years there was turned into the city treasury, as receipts from the gas bureau, the sum of $14,790,404.25, or almost three million dollars in excess of the entire expenditures ($2,881,244.86). In the mean time the price of gas had been reduced from $1.50 to $1.00. But that is not all, for during the same four years there had been furnished free for lighting the streets and municipal offices 2,407,308,398 cubic feet of gas, which, at the same rate that citizens were charged, would amount to $3,299,122, thus making in four years a net profit to the city of $6,180,366.86.

This shows that instead of a loss of $700,000 per annum, as estimated, the city made a clear profit in cash per annum, averaging $1,545,091.71. Surely this is anything but a sad failure; and this, bear in mind, is based upon the official figures—the money actually paid over, and the gas actually furnished for municipal use, and not upon the estimate or guess of interested parties.

It is true as stated that private parties have been seeking to buy the city plant, it being stated that in February of last year a Philadelphia syndicate had offered $20,000,000 for it. They could well afford to pay much more than that, for at the same rate of profit that it has paid the city during those four years, the works would pay for themselves in less than thirteen years, even if there was no increase in the consumption of gas, but which increases constantly.

It is but fair to presume that the estimate and statements made before the committee were so made in the interest of these very parties or others who seek to discredit the city management and compel it to sell that they may get control of the gas works, and in the interest of the contending political mongers, who, as is well known, have long been charging each other with fraud in the management of city affairs.

No doubt the present works, built years ago, could be duplicated at less cost, but so could the gas works of every city in the country. That is no reason why the city should deprive itself of over a million and a half of revenue per annum, and enable a syndicate to take that much or more from the public and put in into its own pockets. The fact that a private company has for the past seven years furnished a portion of the gas for 37 cents per 1,000, shows how profitable the manufacture of gas is, especially water gas, which is now generally furnished, and what an outrage it is to charge the public the prices usually paid.

The reason why the city buys a portion of its gas, is simply because the city works could not supply all that was required for the city and its outlying suburbs. The question of increasing the plant was being considered when this company came in and offered to furnish gas for 37 cents, which offer the city accepted, and made a contract for five years. When that expired the question again arose, but the company had sufficient influence with the city council to prevent anything being done to increase the city plant, and their contract has been continued; but they furnish but a small portion of the entire quantity of gas used, not near one-half, as stated.

I have no doubt that a private company would manufacture gas cheaper than the city does, but the city or citizens would not be benefited a penny; on the contrary, they would be injured to just the amount of the profit now made by the city, as every one can see; but, even if a fact, that does not justify giving to corporations or trusts a monopoly of supplying the public with one of the necessities of life, at a price far above what it ought to be furnished for, as is now done in most of the cities of the country.

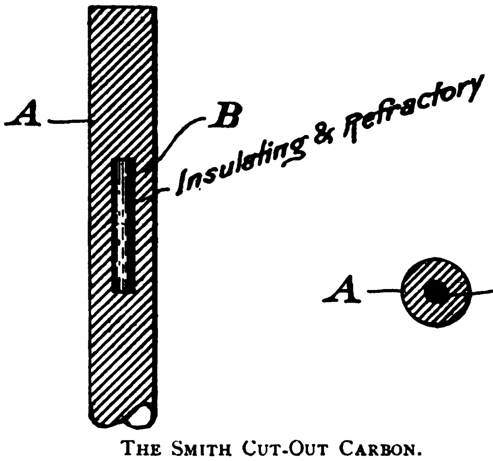
Washington, D. C.

SMITH'S CUT-OUT ARC CARBON.

In spite of the fact that arc lamps are provided with automatic cut-outs, to protect the lamp in case the carbons burn too short, the fact remains that carbon holders are frequently destroyed owing to the failure of the cut-outs to operate. This is especially the case with enclosed arc lamps or single carbon lamps used for interior lighting since these lamps are apt to be trimmed irregularly.

In order to make the cutting out of the lamp absolutely positive, independently of the lamp mechanism, Mr. James D. Smith, of Washington, D. C., has invented a type of carbon which contains within itself an automatic cut-out, as it were. This is accomplished by incorporating in the carbon a piece of insulating and refractory material, such as burnt fire clay, to interpose itself in the path of the arc and extinguish it.

The accompanying engravings show the new carbon, in longitudinal and cross section, A being the carbon proper and B the refractory insulating material. The position of the cut-out is between the place where the carbon is grasped by the carbon-holder and the arc end of the carbon. When the lamp is in operation, the arc consumes the carbon as far as the cut-out, which then interposes itself in the path of the arc and extinguishes it.



The Smith Cut-Out Carbon.

It will be evident that there is no need to make positive and negative carbons of this kind of certain lengths when trimming, for they will automatically cut out the lamp before the arc reaches the carbon-holders. As a result also the carbons can always be entirely consumed, which effects considerable economy.

We understand that the Baldwin Electric Meter Company, of Washington, D. C., is interested in this new cut-out carbon.

BEMENT, ILL., ELECTRIC LIGHT AND POWER COMPANY say: "Your paper is good and instructive and thoroughly up to date."

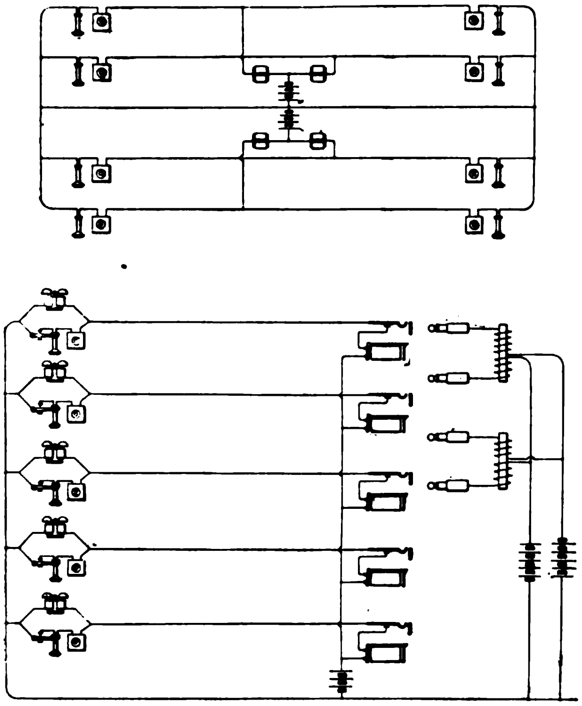
WARRENSBURG, N. Y., ELECTRIC LIGHT WORKS write us with regard to electrical papers: "For us there is none better than The Electrical Engineer."

TELEPHONY AND TELEGRAPHY

THE McBERTY COMMON RETURN TELEPHONE SYSTEM.

ON the so-called common return system of telephony it has been of course impracticable to reduce the resistance of the cross-wire to a very small amount on account of the cost of metal for the conductor. Hence such systems have been subject to cross-talk between different lines simultaneously in use, one line or group of lines acting in joint with the return-wire as a return for another line.

In a system recently devised by Mr. F. R. McBerty, of Chicago, the inventor aims to attain the equivalent of a reduction of resistance of the cross-wire by connecting to the different lines sources of current of opposite polarity, the lines being separated into suitable groups for this purpose, whereby in a considerable group of lines in use at the same time a tendency to produce a condition of no potential at their common junction with the return-wire may be created.



FIGS. 1 AND 2.—THE McBERTY COMMON RETURN TELEPHONE SYSTEM.

In this system the ideal condition would be that shown in Fig. 1, in which the lines are connected together for conversation in pairs, whose inner ends are connected to the different sources of current, the currents being equal in the two members of each pair. Under such a condition no difference of potential would exist between the two ends of the return-wire, and the resistance of the wire would be perfectly eliminated.

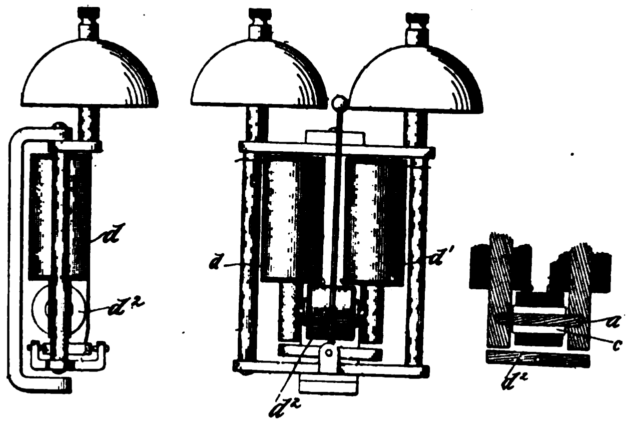
Under more usual conditions of a telephone exchange the different lines are not normally connected with sources of current for the supply of their substation transmitters, but become connected with such sources through the plugs and plug circuits for uniting different lines. Commonly a repeating coil is included in each plug circuit to effect the conductive separation of the lines in order that the line of lower resistance may not divert the current from its mate of higher resistance. In such a system Mr. McBerty contemplates the use of sources of current in the manner before described, one pole of each battery being connected to one member only of each pair of plugs. Then of two united lines one derives current from one pole of one of the sources, while the other derives current from the opposite pole of the other source as shown in Fig. 2. Thus in such a system also the connection of lines in pairs by means of plugs and plug circuits would result in a tendency toward a condition of no difference of potential between the terminals of the return-wire of the lines.

In ordinary exchange practice it would not be practicable to run a single return-wire to all the stations of the system, nor to have the points of connection of the line wires and return-wire identical. The proper grouping of lines likely to be used in connection with each other with a common return-wire for attaining the best results with Mr. McBerty's system would be a matter of judgment.

SCRIBNER'S TELEPHONE BELL MAGNET.

ON a recent patent issued to Mr. C. E. Scribner, of Chicago, that inventor describes a polarized signal-bell for telephone lines which remains undisturbed by current continuously flowing through it, but is sensitive to alternating signaling currents.

The essential novelty of the bell, shown in the accompanying engravings, Figs. 1 and 2, consists in adding to an electromagnet a bridge or magnetic shunt a, Fig. 3, between the poles of the electromagnet and a magnetizing helix upon the bridge, d^2, adapted to nullify the polarity of the magnet poles, or, in other words, to create a condition of no difference of magnetic potential between the poles. The armature, b, is by this device perfectly shunted by the bridge while continuous currents traverse the magnet helices.



FIGS. 1, 2 AND 3.—THE SCRIBNER TELEPHONE CALL BELL.

For the purpose of making the magnet responsive to alternating currents this bridge is surrounded by a closed conducting circuit, as by a tube of copper, c, by which rapid fluctuations of the induction in the bridge are obstructed, so that when the magnet coils are traversed by rapidly varying currents the null condition of the magnet poles is not attained, and the poles act upon the armature in the usual way to effect its movement.

Coils d, d^2, and d' are connected in series. The coils d and d' may be of the usual size and resistance—say of one thousand ohms. Coil d^2 may be of any suitable resistance, but should have a magnetizing effect with relation to coils d and d' such that it may produce in the bridge a' an induction equal to that produced by coils d and d' in the core a, and in the same direction in the circuit.

INDEPENDENT TELEPHONY IN DETROIT.

A SPECIAL dispatch from Detroit, Mich., of June 9 says: The Detroit Telephone Company, now well established as a rival to the Bell, is meeting with most remarkable success. More than 3,000 telephones are connected and in running order, and 4,000 are promised to subscribers by July 1. Thirty days after that all of the 4,700 'phones contracted for will be in place, and the Bell people will find themselves in an inferior position in the telephone business in a town where they have long ruled supreme at exorbitant prices.

The Detroit company has made a uniform price of $25 for residences and $40 for business places, and has taken three-year contracts in every case. Metallic circuits over copper wires are furnished to every one, and the boxes are of oak, large and handsome. The Bell has met the competition only where there are six people on a line, prices for independent wires remaining the same. The 'phone used by the Detroit company is largely the invention of its own engineer, who has patents pending that he declares will make them absolutely independent of the Bell people. President Holmes, however, says the granting of this patent seems to him of small importance, as in the first place he does not believe the Bell company can be forced into commencing suits, and that if it does it is as sure to be beaten as the sun is to shine.

For a time there were complaints of poor service, owing to the confusion of rushing such a vast number of wires in on a new switchboard, but for some weeks the service has been nearly if not quite equal to that of the old company. The switchboard in use is a marvel of convenience, and is also the invention of the company's engineer.

In connection with the Detroit company there has been formed the State Line Telephone Company, which is rapidly pushing copper toll lines into the State. The only one completed is to Mt. Clemens, with a cut of 60 per cent. in the tolls. Big gangs of men are now placing poles between here and Monroe, for use on the Toledo line, and an equally large force is pushing for Jackson via Ypsilanti and Ann Arbor. Every line built will connect with the Detroit line and furnish a fine income under traffic agreements. The new system is an unqualified success.

The contracts the Detroit company now has, if it got no more, insure it a handsome surplus for the coming year, after paying running expenses, interest on bonds and a very fair dividend on stock, so President Holmes declares.

POLE CLIMBER AND POLE SINKING TOOL ON THE U. S. MILITARY TELEGRAPH LINES.

BY CAPT. W. A. GLASSFORD, U. S. A.

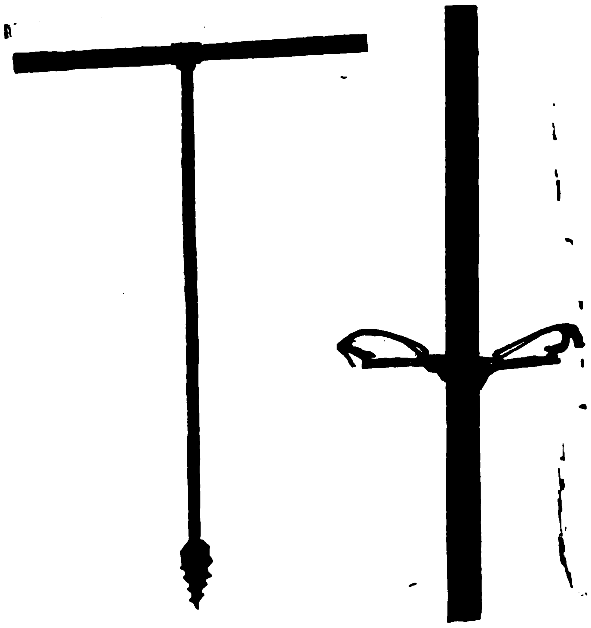
THE military telegraph lines of our army have been factors of no little importance, not only in the administration of the army, but in assisting to develop the mining and other interests of the frontier. Formerly, two systems of military lines extended from the Missouri River to the Pacific, almost paralleling the northern and southern boundary lines. Branches from these and from the commercial wires along the Union Pacific Railway reached about every army post from the Gulf of Mexico to British Columbia. The moving wave of emigration to the frontier settlements and the principal mining camps has been overtaken by the building of other trans-continental railroads and branches with commercial telegraphs.

With this construction of the better means of transportation and of communication of intelligence, the military lines, which were mostly of a semi-permanent nature, have largely given way. Yet, with many of the army posts, especially those near Indian reservations, the military telegraph remains as their only means of rapid communication. These military lines of telegraph are usually built along routes or trails over which few pass except the Indian, the freighter, and occasionally officials of the government. The country thus traversed is mostly desert or prairie plains, and forest covered mountain passes. In both, the prairie or forest fires would be destructive to wooden poles, while in the desert, wooden poles are tempting fuel for the camping freighter. To provide against the liability of such consuming fires, the supports for the military lines are of tubular iron. These iron poles are 22 feet long and 2½ inches in diameter, and each weighs about 75 pounds. Such poles are lighter than wooden ones and much less bulky; they are easily transported on cars and wagons and readily "snaked" along trails up mountain passes.

But in building and repairing, both of which are done by soldiers, it is necessary to climb these slender and smooth poles—a somewhat difficult operation. Various means to accomplish this have been improvised, such as utilizing wooden and rope ladders, which are attached to the iron cross-piece that passes through a hole in the pole, about 4 feet from its top, and which serves the purpose of a foot-rest. These permanent foot-rests, while serving the requirements of a support for the builder or repairman when attaching the wire to the insulator, have to be reached, if not by climbing, by means of a ladder; and they offer a tempting object to the half wild Mexican vaquero or the festive cowboy of the region through which the line passes, for testing his skill with the lariat and the strength of his horse in bending the pole. It was to overcome these objections that the Signal Officer when constructing a line along the Arizona-Mexico border last autumn, described in The Electrical Engineer of December 30, 1896, conceived the idea of a pole climber which would do away with the foot support as well as with the difficulty in climbing.

Such a climber is shown in the accompanying engraving, and consists of a collar of wrought iron, in two semi-circular halves; two steel foot pieces, two bolts for holding the collar and foot pieces together, and two toe straps. All the parts can be readily made by any blacksmith. The wrought iron collar is held close to the pole by two bolts which pass through the ends of the halves, at the same time passing through the two steel foot pieces. The foot pieces are about 7 inches long and bent at the inner end which is serrated to form a dog; these foot pieces are fulcrumed upon the bolts, and when in a horizontal position, the serrated ends clutch the pole, but when lifted, permit the whole device to be moved up or down the pole readily. The toe straps can be made of wire or leather and enable the toe to raise the foot pieces and thus release the grip of the dogs upon the pole. A convenient locking bolt permits the device to be readily and quickly placed about the pole and secured in position.

The lineman inserts his feet within the straps, and grasps the pole, holding himself to it, then raising the feet by bending the knees he lifts the device upward on the pole, and as soon as he throws his weight upon the foot pieces the dogs clutch the pole and the climber then raises himself erect, regrasping the pole from the new and higher position. By successive movements of this kind he ascends as far as may be desired, and standing upon the device he places the wooden plug into the top of the pole, screws on the insulator and ties the line wire thereto. The lineman can stand on one or both feet as may be desired, shift his position to any side of the pole at pleasure, and, when through, by drawing his feet toward the pole, thus raising the levers slightly, the grasp of the latter on the pole is released and the lineman slides to the ground. This device has been issued to and tested with invariable success by operators and repairmen on the Signal Corps lines in the Military Department of the Colorado, which includes Arizona, New Mexico, Utah and California. The illustration shows these climbers attached to the pole ready for the lineman to ascend.



AUGER AND POLE CLIMBER, U. S. MILITARY TELEGRAPH LINES.

In the construction of military lines, rapidity of erection is often a desideratum, and various means have been employed for the rapid sinking of the poles in the ground. When alluvial soil, free from gravel, is met, the well known post hole auger is usually employed. It is, however, objectionable with a pole of small diameter, because the pole is so small as to prevent the insertion of rock around the pole as well as tamping when filling the hole. A device for boring into alluvial soil was made for this work in Arizona, and used in the flats of the Sulphur Springs Valley.

This new device consists of a steel cone, into the base of which is secured an iron shaft about 3½ feet long, the other end of which is provided with a cross-handle similar to that of an auger. The cone, resembling a gimlet, has a steel worm or leading screw beginning at the point of the cone, the threads of which are about an inch apart along the cone, which forms the grooved body. By screwing this cone into the ground the earth is compressed about it, and so a clean hole is made without bringing to the surface any dirt. Into this hole, a trifle larger than the diameter of the pole, the latter is placed, and the pressing outward of the soil by the tool takes the place of tamping. In suitable soil this borer can be used, and a hole 3 feet deep made very rapidly. The tool is shown in the illustration.

AUTOMATIC TELEGRAPHY.—I.

BY PATRICK B. DELANY.

RECENT discussion of the relative merits of automatic telegraphy and the Morse system, and the necessity, from an economical standpoint, for a change in the direction of larger utilization of the carrying capacity of telegraph wires seems to call for more conciseness of claims for the Morse in its various adaptations, and for the automatic system in use, as well as the one proposed.

One would suppose that the speed of simplex, duplex and quadruplex Morse would be reliably ascertained by this time, and that as old and well established a system as the Wheatstone would afford but small range for discussion as to its working, but it seems that the estimates of all these methods vary according to the bias or prejudice of those contending, until there is much the same definiteness about speed estimates as there would be in describing a distance by saying it was "as long as a piece of string."

Unfortunately in this country no one in authority seems to be willing to average up an average day's work with average operators. We have sending tournament records by the Morse which show that 52 words per minute have been transmitted by hand for five minutes. This top notch record was made nearly ten years ago and stands to-day unbeaten, but in justice to other operators who took part in the contest, it must be admitted that the manipulation of this record breaking operator was of a very doubtful quality, and would not have stood the test of accurate reproduction by a recorder.

At the last trial, 1893, with more careful arrangements for proving the quality of the work, five operators reached a speed of 248, 239, 242, 236 and 248 words respectively in five minutes, or an average of over 48 words per minute. An analysis of the words, however, show that they averaged but a small fraction over four letters to the word, while the average for words is fixed at five letters. This would make the actual speed, including punctuations, 41 words per minute, which is certainly a remarkable performance, for on the basis of three impulses to a letter, it calls for over ten impulses per second, or 20 movements of the key, ten down and ten up, and considering that about two-thirds of the impulses were dashes, equalling in time about three dots each, it seems indeed a wonderful achievement. It may appear strange, but it is nevertheless a fact, that an expert operator can make more impulses per minute writing regular Morse with the average number of dots and dashes than when making dots alone.

It seems that expertness in key manipulation and penmanship are equally balanced. No sender can send so fast but some receiver will be able to write it out legibly, and no penman can write so fast but a sender will be found to push him to his utmost. When it comes to typewriting from a sounder it is quite a different matter. The expert typewriter receiver can take his ease with the fastest sender, and can only be pushed by abbreviation of words according to the custom of operators when conversing or transmitting press dispatches or other matter admitting of considerable latitude from the absolute accuracy required in regular messages, and where the text guides the receiving operator. Indeed, it is impracticable for any operator to follow a sounder for any considerable length of time at over 40 words per minute fully spelled out. The strain of concentration would not permit it, while with abbreviations a speed equal to 60 words per minute may be translated by ear and typewritten in full.

Taking 41 words per minute as a well ascertained maximum for the Morse, it does not follow that it is easy to estimate the average speed, for there are no figures on the minimum side. There are no "booby prizes" in telegraph contests. Any sound reading operator can, however, get a fair idea of the expertness of the inexpert by lingering a moment within the sound of an ordinary branch office outfit, or if, while waiting for a train at a suburban station, he lends his ear to the struggle going on over a "way" wire. The fairest deduction from meager facts, observation and speculation on the subject places the average Morse simplex speed at 15 words per minute. As the maximum proves, the system with good wires and expert operators is equal to a higher average, perhaps 25 words per minute, but apparently the telegraph companies do not think that circumstances warrant either one or the other in the majority of cases.

Polar duplex Morse will average about 18 words per minute for each circuit, inasmuch as it not only works quite as well, if not better, than simplex with single current, but because only competent operators are as a rule assigned to these circuits. The quadruplex is also generally manned with able operators, and notwithstanding its lame leg and many other infirmities will probably average 15 words per minute for each circuit.

Taking the quadruplex as the highest development of Morse telegraph in use in this country, and fairly assuming that this system would be used between points where automatic telegraphy would be warranted, 60 words per minute with eight first grade operators over the best wires, for distances not exceeding 500 miles, without repeaters, is a liberal basis for comparison with machine or automatic methods of working.

At present the Wheatstone is the only automatic system in use, extensively in England and to a limited extent in this country, France and Italy. But, as it is not the intention to discuss foreign methods and conditions, the operation of the Wheatstone system in America should, as in the case of the Morse, be alone dealt with.

In the "Telegraph Age," December 16, 1894, Mr. Wm. Finn gives the speed of the Wheatstone duplex between New York and Chicago for 17 days at intervals between May and October, 1893, as 356 words per minute total both ways. As these 17 days were selected from 120, it is fair to presume that they bear about the same relation to the ordinary average speed as 41 words per minute, highest Morse rate, bears to the average of 15, or a little more than double the ordinary rate. One hundred words per minute each way between New York and Chicago is a liberal allowance for the duplexed Wheatstone. Mr. Maver in his excellent work, "American Telegraphy," places it at from 150 to 200 words, very creditable work, considering that it is done through a repeater in the middle of the line. One hundred words per minute on the basis of 5 letters to a word and 3 impulses to a letter requires 25 complete excursions of the relay armature per second in each circuit.

It may be said that best speed attainable with the Wheatstone under most favorable circumstances is 300 words per minute simplex and 400 words per minute duplex. Two impulses, marking and spacing, are necessary for each dot and dash. At 300 words per minute the relay receives 150 impulses per second and its armature must make 75 excursions in the same time. The armature must also do work, either in relaying the signals into a local circuit for operation of the ink recorder, or in making the record direct. In either case the movement of the armature must be considerable to prevent sticking at its contact points, or smudging of the signals on the tape. On circuits without repeaters the average working speed of the different systems in use in this country may be stated as follows:

Simplex Morse	15	words per minute.
Duplex Morse	36	" "
Quadruplex	60	" "
Simplex Wheatstone	125	" "
Duplex Wheatstone	200	" "

The use of a repeater would impair these speeds probably ten per cent. Repeaters are only used to improve the working, but it is for the improvement of a bad condition, or when the wire is too long for direct working.

To some, these estimates may seem low, but they include all the stops and delays, with exception of an actual breakdown to the apparatus or interruption of the line. The Morse sender is stopped and sent back by the receiver. The Wheatstone machine must be fed with tapes.

The proportion of time taken up in this way is difficult to estimate, for as in most things much depends on the man. One incompetent operator on a quadruplex, like a clumsy dancer in a set will demoralize the entire performance, while an inexpert handler of the Wheatstone machine will waste much valuable time.

There can be no question, however, that on the basis of relative speeds there is, owing to "breaks," much more time wasted message for message with the Morse than the Wheatstone.

The methods of timing telegraphs have always been very inexact. Sometimes the number of messages sent in a given time is stated, sometimes the number of words. Neither way affords more than the roughest kind of basis for calculation. One message may be as long as a dozen others. All may be unusually long or unusually short. Words have almost the same degree of variation. Land telegraphy employs words averaging about five letters, while cablegram words average seven. Counting by impulses and spaces on a perforated tape is the nearest approach to accuracy, but not until the spaces between the component elements of a letter are reckoned will true records be available.

The feed row of holes in a Wheatstone tape affords an excellent means of timing, but here the trouble is absence of a uniform basis of calculation. Neither the impulse nor the feed row method answer alike for all systems of automatic transmission. The regular Wheatstone system sends two impulses, positive and negative for each signal whether it be dot or dash, while cable transmitters use but a single impulse. In the regular Wheatstone the time elapsing between the beginning and the end of a dash is represented by blank tape equivalent to the room taken up by three dot perforations, the feed row of perforations being maintained in their unform regularity of distance from each other. From an economical standpoint of utilization of time the system employing a single dot or impulse alike for dots and dashes has an advantage of nearly four to one.

Indeed, it is hard to conceive of any more efficient utilization of the signalling capacity of a line than by the use of a single impulse for a dot or dash. No improvement is possible by the dot and dash code, nor can it ever be approached by any single impulse to the letter sytem, owing to the time required in the span between selections of letters, such as occurs in sending the word "Aztec" for instance; the time required for the gamut of the entire alphabet is consumed in sending the first two letters. The word "bay" by this or any other revolving type wheel system would require the time of 50 impulses or letters to print, while with the dot and dash single impulse plan, it could be transmitted in the time of twelve, allowing the time of one impulse for spacing the letters. Although the dot and dash code averages three impulses to the letter for one impulse for the printer, no time is wasted in rotative selection by the former, and when it comes to the duration of the impulses, the time necessary for operating the electro-magnetic and mechanical parts of the printer is, at 120 revolutions of the type wheel per minute, about twice that required for recording an impulse by the Wheatstone system, and this rule as a matter of course, applies to all the impulses represented by letters interposed between those utilized.

THE BURKE SYSTEM OF CABLE TELEGRAPHY.

AMONG the patents recently issued is one to Mr. Charles G. Burke, of this city, which is so radical in its departure from present methods that it cannot fail to excite keen inquiry on the part of all who are interested in telegraphy. Mr. Burke's invention has for its principal object the adaptation of Morse work to long submarine cables and other telegraph lines where large static capacity is an obstacle to the use of ordinary Morse signals. It also enables messages to be automatically relayed from cable to cable thus doing away with the translation and retransmission of signals now a necessity whenever messages are required to pass over two or more cables.

According to the Burke system, the signals recorded at the receiving station are not caused by the electrical impulses which are transmitted over the line, nor do they correspond with them, but they are made by and result from the action of local mechanical means, which becomes operative only during the intervals between the passage of impulses over the line and after such line impulses have ceased. The impulses are all of uniform duration and need occupy no longer time than the accomplishment of their purpose, which is to momentarily make and break the local circuit which controls the recording mechanism. The impulses simply define the beginning and ending of time, periods which are predetermined to correspond with the dots and dashes of the Morse code. An inked record is made by the recording mechanism of these time periods between impulses, and since they correspond with Morse dots and dashes, so also must their record.

Fig. 1 illustrates a telegraph or cable line with sending and receiving instruments at either end organized to be operated by hand. The keys have front and back contacts and normally the key lever rests upon the front stop, leaving the line free from battery contact. Thus organized, the operation would be as follows: The operator wishing to send would raise his key momentarily from the front contact to the back, thereby sending a current to line which would energize the magnet of the recording mechanism, and momentarily interrupt the ink line normally being made on the receiving tape; in other words, a break would be made in the ink line. The operator would then manipulate the key in the ordinary way. For example, if the letter "I" is to be sent, the operator after lifting the key lever would simply make two dots or two short down and up movements of the key lever, allowing the time of an ordinary dot between the movements. In this way the current is withheld from the line for two short periods occurring between the three up strokes of the key, and the recording mechanism would note these two periods by imprinting on the tape two dots, which would be the letter "I."

If the next letter is to be "N," which consists of a dash followed by a dot, the operator, after letting the key remain down for the time of a space between letters, would again raise it momentarily, and then depress it and leave it down for a time corresponding with a dash, another momentary raise of the key would follow, and then a depression for a dot period followed by a final rise and fall of the lever.

This manipulation of the keys would, of course, at first be attended with some difficulty and would need more or less experience, consequently automatic operation which involves no operative skill is preferable. In Fig. 2 is shown a form of perforated tape for automatic work, together with the record as it would appear in the receiving office. In this form of perforation, the spaces between letters and words are indicated by inked marks readily distinguishable on account of their extra length from dashes. This form of isolation of letters and words secures absolute accuracy, because no misleading combination of the parts of any two approximate letters can be made, and the end of completed words is made unmistakable. In code and cipher messages this form of separating the letters and words would be very valuable.

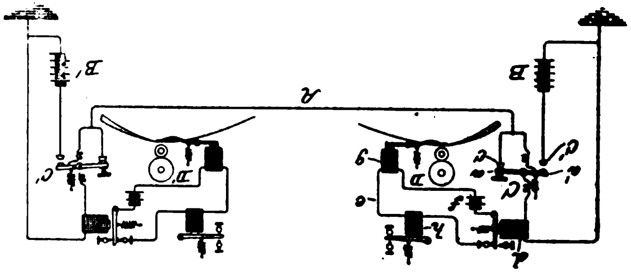


FIG. 1.—BURKE'S SYSTEM OF MORSE CABLE SIGNALLING.

Mr. Burke has devised a perforator specially adapted for preparing this automatic transmitting strip. It is arranged so that the touch of one key will produce a perforation required to transmit a dot, while the touch of a second key produces a dash perforation; a third produces the perforation for spacing between letters and words. Any one familiar with the operation of mirror or siphon recorder keys can operate this perforator without any further experience whatever, the speed being limited only by the operator's skill.

For those who are not familiar with telegraphy or who do not understand the combinations of the Continental Morse code, Mr. Burke has provided a lettered keyboard to be used in combination with his perforator.

An examination of the perforated strip and record illustrated in Fig. 2 will show that the dots and dashes in the record do not correspond with the holes in the transmitting tape, but with the blanks or spaces between them, and since these holes in the tape produce the impulses over the line, the spaces between them must cause breaks in the contact of the battery with the line corresponding with these spaces. The blanks in the record will be found to agree with the holes in the perforated strip and they indicate the impulses over the line. If the line impulses were recorded they would appear as shown at "T," and in such case the blanks between them would constitute the signals. Thus, it will be seen that in this method under no circumstances do the impulses over the line ever become a signal or part of the record, but that in all cases the signals consist of recorded periods of time corresponding with the elements of the Morse code and during which the battery has been withheld from the line.

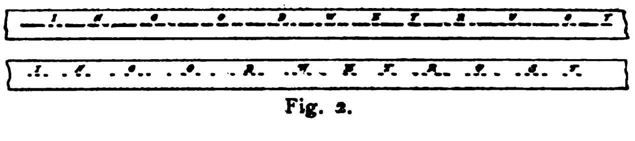

Fig. 2.

As the preparation of the transmitting tape involves no previous experience and since its operation through the transmitter is purely mechanical and automatic, the only actual knowledge required for telegraphing under this new system is sufficient acquaintance with the Morse code to be able to construe the recorded signals.

A complete set of perforating, transmitting and recording instruments adapted to this new system are now being shown at Mr. Burke's office, 48 Broad street, and in combination with one of Mr. Burke's latest improved cable relays they are being operated over an artificial line, presenting and exhibiting the full retarding and characteristic effects of a line of equal resistance and full static capacity of the longest cable now in use. To any one interested in this branch of work a visit to Mr. Burke's office cannot fail to be interesting.

HERTZ WAVE TELEGRAPHY BY THE MARCONI SYSTEM.

(From our London Correspondent.)

At last the truth about the "Marconi mysteries" has been revealed. In a lecture at the Royal Institution on June 4, Mr. W. H. Preece told us what the Marconi invention really is—and a great many other things as well which we knew before. The sensational articles in the lay magazines and in the daily papers ascribed to Marconi the discovery (or invention, as it was perhaps more appropriately termed) of a new kind of electrical radiations which had quite different properties to Hertz rays, which would penetrate anything from a brick wall or a few hundred yards of solid hill to iron plates a foot or so in thickness and blow up the powder magazine of an enemy's ironclad, and do several other truly remarkable and characteristic feats. Marconi has actually devised a very sensitive and seemingly reliable form of coherer, which can detect Hertz waves generated by a Righi radiator several miles distant.

Marconi no doubt deserves great commendation for having worked out an ingenious and efficient apparatus, and having brought us a step nearer to the practical utilization of Hertz waves; but the fact of his abstaining from stating in the interviews and articles that have been published that his work has been nothing more than modifications in the details of apparatus devised by his more illustrious predecessors, has entirely prevented him from receiving that genuine tribute of praise, which almost amounts to veneration, usually accorded so freely to successful workers in the realms of science.

The Marconi coherer consists of a small glass tube four centimetres long, into which two silver pole-pieces are inserted, separated from each other by about half a millimetre. This thin space is filled with a mixture of nickel and silver filings—96 per cent. of nickel, 4 per cent. of silver and a trace of mercury. The tube is exhausted to a vacuum of 4 mm. and sealed. It forms part of a circuit containing a battery cell and a sensitive telegraph relay. Normally the resistance across the powder gap of the receiver is several thousands of ohms, but when the Hertz wave falls on it, it is reduced to about 5 ohms.

Mr. Preece did not say whether the increased sensitiveness of the relay was chiefly due to the composition or the finely divided state of the metal filings, or to the use of a vacuum. In other respects the coherer does not differ very much from that devised by Lodge some four years ago; the principle was first shown by M. E. Branly in 1890. The main defect in the Lodge coherer was that after receiving a wave it did not "decohere" without being shaken or tapped. Marconi gets over this difficulty by putting in the "local" circuit of the relay a small electrically worked hammer, so that on the reception of each signal the glass tube is lightly tapped. The sound made by this little hammer upon the glass is sufficient to read Morse signals from, but, of course, a Morse ink writer or any other instrument can be put in the local circuit.

The transmitter is, as already stated, Prof. Righi's form of Hertz radiator. Two spheres of solid brass, 4 inches in diameter, are fixed in an oil-tight case of insulating material, filled with vaseline oil, so that a hemisphere of each is exposed, and the other hemisphere is immersed in the oil bath. The oil seems to maintain the surfaces of the spheres clean, thus obviating the frequent polishing required in the original apparatus of Hertz. Mr. Preece also stated that it impresses on the waves excited by the sparks between the spheres a uniform and constant form. Two smaller spheres are fixed close to the opposite sides of the two larger spheres, and these smaller ones are connected to the secondary of the induction coil. Morse signals are made by a key in the primary circuit of the coil. The waves produced by this apparatus are very short, generally about 120 cm. long. With a 6-inch spark coil, signals were transmitted to a distance of four miles; for greater distances sparks up to 20 inches were used. Mr. Preece has succeeded in transmitting signals over a distance of eight miles across the Bristol Channel with the Marconi apparatus.

For shorter distances the poles of the coherer are connected to two "wings" of copper, each in series with a small retardation coil. When signalling over longer distances the wings are removed, one pole of the coherer is connected to earth, and the other extended to the top of a mast or by a kite connected with aluminum wire to the coherer. It seems that during the experiments signals were actually received through hills. Mr. Preece explained this by a diagram in which the electric ray was depicted curving round the top of the hill in a very accommodating way. It would seem more probable, however, that, as the beam is naturally somewhat diffused, some rays may be reflected round the sides of the hill by other conducting obstacles, or perhaps the hill was actually not a good enough conductor to absorb the rays, and was to a certain extent transparent to them. Another "apparent anomaly" was that Marconi's relay acts even when enclosed in a metal box. During the lecture Mr. Preece put the instrument in a galvanized iron dust bin, and yet it received the signals transmitted from another room. He also assured his audience that he had performed the same experiment in a hermetically sealed box. This would only prove, however, that the coherer is extremely sensitive and that the intensity of the waves transmitted is so great, that they are not entirely absorbed by the fraction of an inch of metal.

Besides intending to employ this system of telegraphy to signal to lightships and lighthouses from the shore, Mr. Preece intends to use it for a regular public telegraph service to the island of Sark, in the English Channel, as this island is at present not connected to any submarine cable.

When Marconi's patents have been published an interesting question will be whether they have any commercial value. We believe that the use of a vacuum in a coherer has been proposed and even used before. The combination of a coherer with a relay is no new idea, and Lodge proposed in 1894 the employment of an electric vibrator to act as what Mr. Preece calls a decoherer. Moreover, without wishing to lessen the credit due to Marconi, we cannot but think that had the British Telegraph Administration given one of the great English physicists like experimental facilities, the same, or even better, results would have been obtained.

TESLA'S TELEGRAPH TO MARS.

Discussing methods of telegraphing to Mars, Mr. Nikola Tesla says: "The inhabitants of the planets, Mars, for example, must have intelligence. Their life must be made up of events. They must have a conception of time. And therefore they must have means of measuring time, of recording events. Without that they could have no history.

"Thus upon a mathematical basis I believe a system could be founded which in the course of time could be developed into an intelligible code, capable even of conveying the most intricate communications. There is no limit to the possibilities of its development.

"It is upon the result of that calculation that I base the declaration of my belief that a serious attempt at transfer of intelligence to Mars will be made within a short time. Of course, I mean 'short' in the scientific sense. But I would not undertake to say how short or how long that time will probably be."

MUNICIPAL TELEPHONE PLANT NOT WANTED AT SAGINAW, MICH.

Several weeks ago the council at Bay City, Mich., passed a resolution looking toward the establishment of a municipal telephone system jointly by the Saginaws and the two Bay Cities. A committee of five aldermen and five prominent business men was appointed to confer with like committee from the other valley cities. This committee never got together simply because Rep. Donovan frowned on such a municipal plan and had stricken out in the charter bill the section which gave Bay City the right to go into such a deal. The Saginaw council and Board of Trade took the matter up, however, and the following is the report:

The joint committee of the Saginaw common council and the board of trade to whom was referred the question of constructing a municipal telephone plant, respectfully report that we have fully considered the matter, and are of the opinion that it would not be advisable for the city to construct, own and operate a public telephone system. In the first place, the building of such a system would cost about $100,000, and this would have to be borrowed on bonds of the city. There are other reasons which make the scheme inadvisable and which will readily suggest themselves to business men generally.

In thus deciding we do not wish to be understood as discouraging the independent telephone movement, which now seems to be spreading over the country, but, on the contrary, we would recommend to our citizens careful consideration of the merits of the new Valley Telephone Company, recently organized to construct a telephone system in Saginaw, Bay City and West Bay City. This company is now duly incorporated under the laws of Michigan, with some of the prominent business and professional men of Saginaw and Bay City as officers and directors, and it is entirely a home enterprise. It would seem that this organization is the more properly designed to construct and operate an independent telephone system, and it also affords a field for investment by those of our citizens who have the capital, and serves to keep this capital invested at home.

TELEGRAPHY AND THE INCREASE OF WESTERN UNION STOCK.

THE application to the New York Stock Exchange to "list" an additional amount of $2,000,000 of the Western Union Telegraph Company's stock was the first intimation the financial or speculative public received that such action was contemplated by the company. It is stated that the entire amount of the new stock has been sold to Messrs. J. P. Morgan & Co., though the price is not stated, and the further information is given out that the proceeds are to be applied in liquidation of the floating debt, resulting from large expenditures for betterments and additions to the property in the last three or four years.

It will be recalled, says Bradstreets, in discussing the situation, that in October, 1892, the company increased its authorized share capital by $13,800,000, making the total $100,000,000. Of this increase $8,620,000 was distributed in the same year just named as a 10 per cent. stock dividend to the shareholders to represent net earnings which had been devoted to the extension and improvement of the property. A further amount of $550,000 stock was since issued to pay for the American Rapid Telegraph Company's property, and these amounts, with the $2,000,000 more just sold, bringing the outstanding stock of the Western Union up to $97,370,000.

In the explanation of the new stock issue it is stated that the company since 1892 has made additions and betterments to property costing something like $4,000,000, a large part of which was, of course, been provided from net earnings, the surplus over dividends in the last four years ($2,687,000) being mainly applied to such purposes. Among the details of the new construction it is stated that there have been added to the plant 2,681 miles of poles, 88,238 miles of wire, at a cost of $3,133,000, and a new building in the city of Chicago, purchased and owned by the company, the expenditure for which was $1,666,000. It is understood that the company has built a good many new extensions in the West during the period under consideration, and hence the creation of a floating debt, which it is the purpose of the new stock issue to extinguish.

These developments are interesting, coming as they do just after what would seem to have been some internal friction in the company's management in regard to the dividend policy. On the day the new stock issue was announced the executive committee of the company recommended the declaration of the regular 1¼ per cent. quarterly. This was fully expected, though a few weeks back the "Street" generally believed that a reduction from a 5 per cent. to a 4 per cent. annual dividend basis was altogether likely. During the period of business depression the traffic and business of the Western Union Telegraph Company had necessarily suffered, while the threatened refusal of the New York Stock Exchange to renew the contract for the distribution of its quotations by the Gold and Stock Telegraph Company, a concern controlled by the Western Union, would cut off a very important source of revenue from the latter. It will be recalled that the action of the Stock Exchange in this connection is part of the general programme of warfare on the bucket shops, "syndicates" and other speculative pests, and the charge was freely made that the Western Union's policy has been to furnish quotations to all applicants, or, in other words, to consult only its own financial interests. Hence the loss of the contract and the determination of the exchange to regulate the quotation service in a much stricter manner. Furthermore, it will be recalled that the position of the Bell Telephone Company in regard to telegraph service was the object of some doubts, since the system of long-distance wires that organization controls could be utilized for the establishment of regular telegraphic service throughout a large section of the country. The rumors in this connection proved, however, to be exaggerated and unfounded, the management of the Bell Company indicating no disposition whatever to enter the telegraph business. On the other hand, it is to be remembered, that the competition of the Postal Telegraph Company becomes more effective from year to year, as that company's system of lines is steadily extended, and secures a growing proportion of the general business of the country, the latest move, by which the land lines of the Postal Company were consolidated with the Commercial Cable Company, making a still stronger organization. At the same time the Postal and the Western Union have for some years gotten along in complete harmony, and no rate cutting has taken place. It would now seem that the "Street," indeed, took an exaggerated view of the troubles to which the Western Union was exposed, and that any internal divergencies of views have been adjusted by the transaction that was made public this week, the effect of which would be to leave the company's surplus earnings free for the maintenance of dividends.

MEETING OF INDEPENDENT TELEPHONE [illegible] IN BOSTON, JUNE 17.

PURSUANT to a circular sent out from the office of Whitman & Couch, manufacturers of Swedish telephones, on May 25, a meeting was held June 17 at the office of that firm, 196 Summer street, Boston, Mass. The call was for a meeting of the independent telephone interests of the East with a view of ultimate organization for mutual protection in case of a suit being brought by the Bell Telephone Company, and also for the purpose of sending delegates to the meeting of the national organization which is to be held at Detroit, June 22, 23 and 24. While no organization was perfected at the meeting this morning, considerable business was transacted, and the views of the representatives present were thoroughly aired. It was the unanimous opinion that the time was ripe for concerted action on the part of the independent telephone interests, and it was thought that it would be better to await the action of the national organization before taking steps to form an association in the East. Two delegates were selected to represent the meeting at Detroit and funds were subscribed to defray their expenses. About two hundred replies have been received from independent exchanges and manufacturers in the East and South, and with but a single exception, they express their pleasure at the proposed movement and offer their support when an organization shall have been formed.

Mr. Raymond L. Whitman called the meeting to order and explained the nature of the business to be considered. There were about twenty representatives present. "The time is ripe," said Mr. Whitman, "for the formation of some sort of a combination where we can go into the field with a solid and substantial backing. I do not think that any one company should be forced to bear the brunt of a suit. The Bell Company has the capital and the best talent to represent it, and we should stand together. At a time like this, independent machines and companies should be thrown aside, for there is plenty of time for competition when this thing is settled."

Mr. Whitman was elected chairman of the meeting, and Mr. Spofford, of the Haverhill Telephone Company, was chosen as secretary. Mr. Whitman then continued his explanation of the movement, saying that the exchange people are much hampered in rentals and in getting subscribers and also in getting capital interested; and as for the manufacturers they cannot protect buyers. He proposed that a subscription be started and the funds placed in the hands of a board of trustees, the funds to be devoted to defending any suit that may be brought; it would be, in fact, an insurance. In answer to a question he stated that it was his idea to have the delegates elected to attend the meeting in Detroit to represent the members of the association in the East. He called upon J. D. Leatherbee, representing the National Telephone Company. Mr. Leatherbee detailed at length the position of his company in the suit instituted by the Bell Telephone Company in August, 1895. He said that it was the old story of David and Goliath. It has been the desire of the company to prolong the litigation as far as possible in order to secure united action. He said that he had felt from the first that the Government suit was a farce. He found that the lawyers versed in telephone philosophy were unreliable. In the selection of lawyers loyalty was the first requisite—ability the second. "I desire to say," he continued, "that I am in hearty accord with any body of men who possess sufficient stamina, mentally and physically, to compel the Bell Company to come down from its high perch and let us alone. This meeting is on the right track and should send two delegates to Detroit. The Western and Southern people feel differently in this matter. We are inclined to be conservative and will submit to a great deal before we take action. I believe that this infamous, so-called patent—the Berliner—can be beaten."

W. C. Watts, representing the Stanton Mutual Telephone Company, of Stanton, Va., said that he had come to the meeting for information and wanted to hear further discussion. Secretary Spofford made an address. J. Merrill Lord, representing the Maine Rural Telephone Company, said that he did not believe that the time was ripe to form a permanent organization. He believed that the action of this organization must, in a large measure, depend upon the action of the national association. The method of raising money, he thought to be a secondary matter.

After some further discussion the following-named delegates were elected to attend the meeting at Detroit: J. D. Leatherbee, of the National Telephone Company; and S. H. Couch, of Whitman & Couch. Mr. Leatherbee said that he did not think that the delegates should go to Detroit and say that they represented an Eastern organization. It would be better that they go as individuals representing the individuals who had gathered at the meeting this morning. The meeting was then adjourned to await the report of the delegates after the meeting at Detroit.

TELEPHONY ON THE NEW YORK STATE CANALS.

Superintendent of Public Works G. W. Aldridge, of Albany, N. Y., is taking active steps in establishing a system of telephonic communication on the canals, for which purpose the Legislature has appropriated $100,000. The scheme is entirely original with the department of public works and was suggested by the difficulty which is often experienced by the department at Albany on reaching various parts of the canal with which immediate communication is imperative. Superintendent Aldridge advertised for bids for the work as soon as the appropriation was available, with the intention of completing the same to the extent of the appropriation.

The proffers received from this advertisement embraced two separate plans for the system, differing in details only, and they indicated that the entire work would cost $150,000. No bids were accepted at that time on account of the smallness of the appropriation. The recent Legislature appropriated an additional $50,000, and it is Superintendent Aldridge's intention to advertise within a month for new bids for the work, and as soon as they are received the contracts will be let and the work commenced. He hopes that the Legislature of 1898 will appropriate the third $50,000 so that the work can be completed.

LIMITING DEAD HEAD TELEPHONY IN PITTSBURG.

A special dispatch from Pittsburg of June 11th says:—The saloon-keepers and restaurant proprietors are also aroused over the recent order of the Bell telephone people, forbidding patrons of such places the free use of telephones. The stand taken by the hotel men to order out telephones has encouraged them, and it is probable that some similar action will result after they have thoroughly sized up the situation.

The Bell Company has thrown tempting bait before each one in the hope of disarming opposition. Each saloon-keeper and restaurateur has been told that he must place an automatic call instrument and pay $60 for 600 calls, or sign an ironclad contract, agreeing to use his telephone strictly for his private business. The bait thrown out is the offer of a commission of 10 per cent. on each call made on the automatic instrument by strangers, or when the regular instrument is used a commission of 15 per cent. is offered.

Some of the saloon-keepers have taken the instruments on these terms, as they claim the contracting agent of the Bell Company told them that all saloon-keepers would be compelled to take automatic call instruments.

President D. F. Henry, of the telephone company, in talking with a reporter on the subject, said that the rule is nothing new or arbitrary, but an enforcement of the contract under which every instrument is taken, as specified above.

"It is to prevent an abuse of the telephone privilege," said President Henry. "We have a number of letters on file from hotels complaining that they cannot get the proper use of their telephones on account of the number of non-subscribers who come in to 'borrow' them, and who consume the time and labor of both the hotel and telephone people. The contract explains itself. It is nothing new, and only seems so because there is an agitation of the matter. The general public has no right to use the instruments. If they have a desire to use them it is only fair to all parties that they go to the booths provided for the purpose and pay 10 cents for the privilege.

"If a person has a hydrant and is paying water rental, would they say to their neighbors, who have no hydrant and are paying no water rental, 'come in, use my hydrant and get your water supply free.' They would not, and there are very few people who would ask for water under those conditions. The cases are similar."

President Henry continued that if a subscriber is going along the street and wants to use a telephone he is entitled to the use of any in the neighborhood. If he tells "central" that he is a subscriber there is no trouble.

"There seems," said the president, "that an impression has gotton abroad that if a subscriber is not at his own individual telephone, the company is going to cut him off from conversation, and make him use the nearest pay station. That is all a mistake, the subscribers and their employés who are counted as subscribers, can talk to subscribers.

"The order now being enforced is simply one to prevent the general public abusing the privileges."

Mr. Henry said the case of a department store that hires a telephone exclusively for public use is different from that of a hotel. In other cities he said the pay stations are used, and he thought there was no use in doing otherwise in Pittsburg. He called attention to the following "caution" which is printed in every telephone directory:

"The use of the telephone by any person not a subscriber to the telephone exchange shall terminate the contract at the option of the company, and shall authorize them to take away the instrument, fixtures and apparatus connected therewith. Subscribers are respectfully requested to notice the above conditions, and to bear in mind that while they are allowing the unauthorized use of the instrument, everybody is cut off from communicating with them. In many instances subscribers have lost important business by allowing the wires to be used improperly. Our patrons are requested to assist us in protecting them from such consequences."

"These rules, which have been in force for years, seem to explain the whole matter," he said in conclusion.

NO LANDING FOR THE FRENCH CABLE.

A special dispatch from Washington of June 17th says:—The President has refused the French Telegraph Cable Company permission to land its lines on Cape Cod or any other part of the New England coast on the ground that similar requests made before by other companies for like privileges have been refused by the Government. One of the last appearances of Mr. Blaine at the Capitol was to submit an argument before the Senate Commerce Committee against granting the right of a French cable line to land on any part of the Carolina coast.

THE STANDARD TELEPHONE COMPANY TO BEGIN SERVICE IN PHILADELPHIA.

A special dispatch from Philadelphia of June 17 says: The Philadelphia Standard Telephone Company, which secured a franchise to operate an independent telephone service, is reported to have entered into a contract with a New York banking firm to raise the capital to complete the work of construction in this city. The work was begun months ago, with capital furnished by a construction company, but it was suspended on account of the business depression. The company, it is understood, intends to enter into rivalry with the Bell Company and let the courts determine the validity of the patent rights it claims. The attorney for the company said to-day that the enterprise would shortly begin operating a local service.

TELEPHONES IN POSTAL SERVICE.

An improvement about to be introduced into the postal service in Boston is that of establishing independent telephones in the central building and at the several stations and substations. For this purpose the department at Washington has granted $4,184, which will be available in time to have the service in operation by July 1. Two trunk lines will be built between the central post office and the telephone central and instruments will be put in in the divisions, stations and substations, so that these places may establish connections with each other and with the outside public, the same as other subscribers.

TELEPHONY AT NELSONVILLE, O.

Mr. L. B. Engle writes us as follows from Nelsonville, Ohio: I have franchises both here and at Logan, Ohio, and will erect telephone exchanges in both places, and connect them with a toll line, the distance being about twelve miles.

The construction work is now under way at Logan and is being pushed as rapidly as possible. That exchange will be started with 100 subscribers; Nelsonville will have about 150. The rates are, for private houses, $18; for business houses, $24, per annum, payable monthly in advance. Long distance telephones will be used, and will be supplied by the North Electric Company, of Cleveland, Ohio.

UTICA, N. Y.—The Standard Telephone Co., of Utica, is to go ahead with the construction of its independent system.

INDEPENDENT STATE TELEPHONE ASSOCIATION OF MICHIGAN MEETING, JUNE 21, 1897, AT DETROIT.

IN connection with the larger gathering for national purposes, of the independent telephone interests, and as a precedent step to co-operation therewith, the anti-Bell companies in the State of Michigan met on June 21, at Russell House, Detroit, and organized a State body for mutual defense and support. It was quite largely attended and the spirit manifested was a good evidence of the feeling prevalent in general.

In calling the Michigan gathering to order W. L. Holmes, of Detroit, briefly outlined the purpose, saying they had come together to get better acquainted and form a State organization. He then called for nominations for temporary presiding officers. For chairman there were two names, that of Mr. Holmes and J. B. Ware, of Grand Rapids, the latter insisting on withdrawing his name in favor of Mr. Holmes, but the convention would not have it that way and Mr. Ware was elected presiding officer by a unanimous vote. Alexander I. McLeod, of Detroit, was chosen secretary. In taking his seat, Mr. Ware made a short address, touching on the importance of the independent telephone movement and the necessity for organization as against their powerful opponent, the Bell Co.

At the suggestion of Secretary McLeod the delegates present handed in their credentials, and the list disclosed the following, forming, as it were, the charter members of the new association and the local exchanges they represent: Charles Flowers, Detroit; Capt. C. Gardener, Dearborn; J. B. Ware, Grand Rapids; C. P. Collins, Wayne; H. C. Hedges, Lansing; Hugh O'Connor, Plymouth; W. C. Sterling, Jr., Monroe; Geo. N. Connor, Mt. Clemens; John T. Holmes, Port Huron; Dr. J. Williams, Jr., Adrian; Justin R. Whiting, St. Clair; George A. Beaton, Jackson; William H. Blake, Cheboygan; H. H. Hatch, Pontiac; E. H. Parker, Flushing; Frank A. Vernor, Memphis; J. H. Fildew, St. Johns; G. A. Weed, Lake Odessa; E. S. Rogers, Owosso; W. O. King, Toronto; J. N. Starkweather and V. O. Whipple, Northville; A. I. McLeod, W. L. Holmes and T. F. Ahern, Detroit; G. D. Bouton, Ann Arbor and Ypsilanti; W. H. Gilbert and S. G. Higgins, Saginaw.

Messrs. Blake, of Cheboygan; Parker, of Flushing; Vernor, of Memphis, and one or two others, reported that they were present as proxies by request.

Judge Hatch made a short address, saying: "The present movement has for its object the organization of the many different local telephone companies of Michigan into an association, so that the people of Michigan can be provided with a serviceable telephone system at reasonable rates. It is not the intention of the organizers to form an association for the purpose of going into court and fighting the Bell Company. That matter will be attended to at the national meeting, which begins to-morrow. What we want to furnish our subscribers, in order to combat with the gigantic monopoly, is a long-distance service. That is one difficulty confronting us, although it has been partially overcome by inter-town communication already established by many of the various State exchanges and the inter-State exchanges are assisting in extending this service. This committee, just named, should discuss and adopt some system of rates and prices, both for local service and for long-distance telephoning. This is the main business before us, also to settle the social questions, the reception of the visiting delegates to the national convention, and to make preparations for their entertainment. The independent telephone companies are now in their infancy, but I am confident, from the interest displayed here and elsewhere, that the time is not far off when our telephones will be in every residence in city and village, and not only that, but no intelligent farmer anywhere in the rural districts will be without a 'phone when it can be given him at a nominal cost of $5 or $6. I understand that in Norway and Sweden this system of farm telephones already exists at a very low rate. The time is coming, I tell you, when all America will have this cheap service extending to even the most remote farm houses. While without doubt all of us here have some individual ends to serve, the fact remains that we are all interested in fighting the Bell Telephon Company and in establishing cheap rates for a good telephone service. In the end I am sure the telephone will entirely supplant the telegraph service. It ought not to take the committee very long to prepare the by-laws and constitution that such an organization as this requires."

The officers of the new organization of Michigan selected are as follows: President, J. B. Ware, of Grand Rapids; vice-presidents, first, W. L. Holmes, of Detroit; second, James E. Davidson, of Bay City; third, George W. Finch, of Escanaba; secretary, Alex. I. McLeod, of Detroit; treasurer, J. H. Fildew, of St. Johns; and executive council, comprising the preceding officers and the following six members: Dr. J. Williams, of Adrian; S. J. Higgins, of Saginaw; F. B. Johnson, of Lansing; Hugh O'Connor, of Plymouth; Hugh Park, of Muskegon; and George Weed, of Lake Odessa.

What one member objected to as "raising the bloody flag against any railroad company," was adopted by the newly-formed association in a report prepared by the Committee on Resolutions, composed of Messrs. John T. Holmes, W. C. Sterling and F. G. Ihmsen, of Three Rivers. Their report censured the Michigan Central, the Grand Trunk and the Flint & Pere Marquette Railroad Companies for entering into a contract with the Michigan Bell Telephone Co., whereby they agree not to use any other telephone or to allow any other than Bell telephones to be used upon their premises, and this works to the disadvantage of the independent companies and their customers. The report came in for discussion, but was adopted overwhelmingly. Similar conditions were reported elsewhere; but at several points, the Grand Trunk and Lake Shore, it was said, were permitting the connection of independent telephones. The resolve to insist on no discrimination was very emphatically asserted.

The constitution and by-laws of the association were prepared by the following committee, elected early in the session: Charles, Flowers, chairman; J. H. Fildew and ex-Congressman Whiting. The object of the association, as stated in Article 2 is: "Mutual protection and connection of all local telephone exchanges and toll line companies in Michigan, and to endeavor to bring about a system of toll line connections with adjoining States." The remaining articles provide for officers and define their duties. Regular meetings are to be held on the second Tuesday of June of each year, with a provision that special meetings may be called by the president.

The annual dues are fixed as follows: Each exchange having 50 or less telephones, $5; 51 to 100, $10; 101 to 200, $15; 201 to 300, $20; 301 to 500, $25; 501 to 1,000, $30; and 1,000 or more, $35. The subject of an initiation fee provoked considerable debate, one member holding that where the exchange embraced farming communities it would be difficult to collect an initiation fee, and this was settled by providing that all dues shall be paid in advance. The president is to receive a salary of $100 and the secretary a salary of $300, while the treasurer is without stipend, although required to give bond.

Just before adjournment Charles Flowers was elected chairman of the Michigan delegation to represent them as spokesman in the convention of the National Independent Telephone Association, to meet on Tuesday afternoon.

Shortly after the convention first met it was deemed advisable to hold an executive session, at which the representatives of the press were excluded. This meeting was devoted to a general discussion of business affairs of the independent companies of the State and in which the methods of the Bell Company were exploited, and condemnation of them was not spared. Mr. Ware, the newly elected president of the association, gave an interesting review of the situation in Western Michigan, especially in Grand Rapids. He stated that the net profits of the Grand Rapids telephone company, known as the Citizens', was $13,000 the first year. He also gave a comparison of the number of subscribers in both the new and the Bell companies, and the mileage of each, together with the class of instruments and the systems used. The methods of the Bell people in cutting rates and in putting in free telephones in residences, following the birth of the independent company, were also dilated upon, and many other operations of the older company were told of. Mr. Ware closed with a statement, giving figures to verify his words, that the independent companies were now running the Bell a close race in Western Michigan, both as to service in small towns and in long-distance telephoning.

The Executive Committee of the Michigan State Association held its first meeting on Tuesday morning, the proceedings being conducted, of course, behind closed doors.

HYPNOTIZING BY TELEPHONE.

THE wonders of the telephone never cease. The latest brought to our attention is the hypnotizing of a young boy through the medium of the telephone at Houston, Texas. It is needless to surmise that the subject was a pronounced cataleptic, but the facts brought to light would seem to indicate more strongly than ever the necessity for a stringent law against the promiscuous practice of hypnotizing. We do not imagine that many persons could be influenced hypnotically over the telephone, yet it will be just as well to guard against such practices by prompt and effective legislation.

JUDGE R. S. TAYLOR.

CHAS. FLOWERS.

JUDGE J. M. THOMAS.

E. H. ANDRESS.

J. E. KEELYN.

MEETING OF INDEPENDENT ANTI-BELL TELEPHONE INTERESTS AT DETROIT, JUNE 22 AND 23, 1897.

FIRST DAY.

THE convention of the independent telephone companies of the United States was called to order at 2:30 p. m. on Tuesday, June 22, at the Harmonie Hall, Detroit, by Hon. Chas. Flowers, of the Detroit Telephone Co., and well known as the Public Prosecutor, who introduced Mayor Maybury, in behalf of the city of Detroit. About 200 were present.

MAYOR W. C. MAYBURY made a brief address of welcome and congratulated the delegates upon their achievements, one being the modern telephone girl, a lady heard but not seen, and whose message ever inculcated patience. The world was continually growing smaller, chiefly by its multiplied means of intelligence, and the telephone had proved itself to be the mightiest among the agencies for bringing men and peoples together. As to the objects of the meeting, they were well understood, and the hearts of the people were with the convention because they knew that their aim was better service and cheaper service.

MR. FLOWERS then made a brief address of welcome as the representatives of the Detroit Telephone Co., one of the largest independent telephone companies in the State and in the country. He remarked that there was continual evolution, and in everything they witnessed changes due to the effort of stubborn, restless and persistent minds, ready to apply themselves to every new task. When the hour came there were men who recognized the fitness of the season and who were prompt to answer the roll call. It had been so in the development of independent telephony, and the men present had shown themselves able to meet the call for an advanced telephone service. They of the Detroit Telephone Co. were justly proud of having, through some tribulation and straits, and in face of many difficulties, established the largest independent telephone system in the United States and put it in successful operation. As representatives of that system, he and his colleagues welcomed the delegates to the city of Detroit and asked their earnest co-operation in the effort to make the independent movement successful.

JUDGE JAMES M. THOMAS, of Chillicothe, O., the president, then acknowledged in a few felicitous remarks the welcome that had been extended, and remarked that the companies gathered had withstood a great deal. Their friends had all questioned their sagacity and business ability in going into the independent telephone movement, to which many things had impelled himself and others. But time and the march of events were justifying them, and the closer they stood together the more successful their campaign would be.

JUDGE R. S. TAYLOR, of Fort Wayne, Ind., one of the Government counsel in the Berliner suits, was then asked to address the meeting and was very warmly received on doing so. He rehearsed the familiar facts with regard to the Government suits to annul the Berliner patent, and urged that the decision of the United States Supreme Court had simply left things as they were before, it having merely declined to cancel the Berliner patent on the ground of fraud. He compared the attempt to extend the life of the Bell telephone monopoly to the action by which, according to Scripture, Jacob, after working seven years to get one daughter, was made to work another seven before he could get her. The American Bell Telephone Co. had been like Jacob's father-in-law, and was the most successful stockraiser that ever sheared lambs; and in the same way it now expected the people of the United States to work for it another seventeen years after having already done so for a full term. The history of this affair he regarded as one of the most extraordinary things in history. The telephone was unmatched in the art of invention during the last fifty years, for nothing came so close to the people. But it had been fully paid for. More dollars might have been spent on other elaborate electrical apparatus, but the American people, in view of the cheapness and simplicity of the mechanism, had paid more for the telephone than for any other invention of the last half century.

As to the objects of the convention, it had been stated in some of the newspapers that the main or sole idea was to fight the Bell Telephone Co. Well, he did not know what the convention as such had to do about it. If some very strong denunciatory resolutions were offered, they would probably receive a very cordial support, but the convention as such was powerless to affect the legal situation, interesting as it doubtless was. The Berliner patent, as it stood, expires in 1908, but he was ready to express his opinion, though it might not be sustained, that the patent was of no intrinsic value and would be declared against on intrinsic grounds of demerit, as it was already by Judge Carpenter. That was not disturbed by any action of the Supreme Court, which simply held that if the Government had been lax in the Patent Office, the Bell Co. ought not to be blamed, but should make the best it could for itself out of the situation. In other words, an applicant in the U. S. Patent Office was entitled to get all the good he could out of the delay of his application.

Judge Taylor said he was sorry for the decision, and did what he could to prevent it, but he was not surprised, as he had intimated some time in advance of the fact that such a decision might be reached. The proposition to the Court was one without precedent, as no patent had ever been set aside upon that ground. It showed again that a plea that is unequivocally morally right and just is not always the law. Besides being the first case thus brought forward by the Government to set aside its own patent, he did not risk very much in saying it was the last they would see. The decision of the court that no question would be entertained by it at all which can be raised by a private citizen in a suit for infringement restricts the ground practically to one, which is that of fraud. Further, the decision that the fraud must be proved by the same kind or amount of evidence which will set aside a horse trade, makes it impossible to make the proof. The patent sharps who control matters of this kind were not such awkward fellows as to make that kind of exposable blunder. The law was now that any sort of indirection in the Patent Office by which you got a patent didn't count if you were not caught at it—and that meant you would not be caught at it. Hereafter, therefore, it will be left for the people themselves to fight out these questions which arose upon the validity of patents.

As to this particular patent the decision of the Supreme Court left it exactly where it was when the patent issued. It is now the fact that the validity of this patent is to be tried in exactly the same way and upon exactly the same proceedings as the validity of patents in general is tried. But nothing which has been said or done by the Supreme Court puts any obstacle whatever to the full and thorough and complete trial of all the questions which can be raised, or have been, against the validity of the Berliner patent, as on the suit of a private citizen in regard to any infringement.

He would say that this attempt to protect themselves and get the patent out of the way in short order had been of ad-

VOL. XXIII. NEW YORK, JUNE 23, 1897. No. 477.

WELSBACHS AND FUEL GAS.

THE recent meeting of the National Electric Light Association found its time so much engrossed with matters of rates and other questions that bare mention was made of the Welsbach burner. This no doubt was a matter of regret among many of the members, who would like to have heard more on this timely subject. There is no need of disguising the fact that electric light companies are watching closely the introduction of the Welsbach burner, and wideawake members of the fraternity are keeping themselves informed as to the progress of this new form of light, the most serious competitor they have had to meet since the introduction of electricity as an illuminant. But what the National Electric Light convention failed to give them in the way of information is supplied by some of the recent meetings of gas associations. That of the Pacific Coast Gas Association afforded an opportunity for the reading of a paper on Welsbach lamps, an abstract of which, together with the discussion, will be found on another page. From the results shown by the author of the paper, it would appear that the Welsbach lamp may be assumed to have arrived to a stage of commercial operativeness, but in the discussion which arose, a very curious point was brought out, which has not probably been so fully considered as it may be in the near future, and that is, the paying qualities of the Welsbach light so far as gas companies are concerned. It is evident that a 2½ or 3-foot burner in lieu of the customary 5-foot tip may be a good thing for the consumer, but we doubt if the gas companies look upon the innovation with the same smile of satisfaction. In other words, we believe it will not be denied that the general introduction of Welsbach burners will mean a serious loss of income to the gas companies. It is, therefore, probably fair to assume that the Welsbachs will not be pushed to the front by gas companies, who can only see in it a curtailment of their profits. So far as street lighting is concerned, the author of the paper above referred to admits that the Welsbach cannot compete against arc lights on streets comparatively free from trees, but assumes that the Welsbachs are better adapted to thoroughfares thickly studded with trees. We do not, by any means, admit the truth of this proposition. Where the streets are actually so heavily shaded that arc lights cannot be advantageously used we believe that a series incandescent lamp system can meet all the requirements of the companies and the public, and can be operated easily in competition with Welsbach, or any other system of gas lighting. Such systems have been, and are still, successfully operated, and with lamps of between 25 and 50 c. p. a result can be obtained which leaves nothing to be desired. This is little else than the old Edison municipal system of direct current incandescent lighting, which, we are sorry to say, has been somewhat neglected. The point we desire to make is that if electric light companies would only study the situation carefully they can furnish any community with exactly the amount and kind of illumination that it desires, and by giving strict attention to the quality of their service, they will be enabled to secure street lighting contracts to the exclusion of gas of any kind.

Looking at another side of the cheap gas question and its possible influence on electric central station supply business, we would call attention also to the paper read recently by Mr. F. H. Shelton before the Western Gas Association, at Cincinnati. This gentleman took for his theme the failure of the commercial attempts to supply fuel gas in the United States, and we must admit that he accomplished his object in a most thoroughgoing manner. Of the twenty-seven enterprises actually built and operated for distributing fuel gas to the public in the United States from 1880 until 1896, it would seem that twenty-two have utterly collapsed. Of the other five, two (Bridgeport and Rapid City) are trying to get out of the fuel gas business, and three (Framingham, Cottage City and Tacony), after six years' operation each, now show less output or fewer customers than before, and never a dollar of earnings returned to stockholders from commercial fuel gas sales. The reason for this, as shown by Mr. Shelton, is not far to seek, since heat in gas form has not, as a whole, been sold any cheaper in the shape of "fuel gas" than it was already sold in the shape of illuminating gas. Hence, the public has been no better off. In other words, the "fuel gases" had an average heat value of between 300 and 400 heat units, while the illuminating gas generally distributed in the cities of the United States ranges between 625 and 750 heat units. It is, therefore, safe to say that fuel gas has seen its best days, so far as its general public conditions of distribution are concerned.

Apropos of the relative economy of electric incandescents and Welsbachs we have before us a report of the performances of the electric lighting plant at the Government Hospital for the Insane, at Washington, D. C., by Chief Engineer G. W. Baird, U. S. N., in which the author makes a particular comparison between gas and electricity. Without going into details this shows that taking lamps at 3.2 watts per c. p. the current employed gave 16,800 c. p. hours for $1.50, or reduced to a dollar basis, 11,200 c. p. hours for $1. Gas at $1 per 1,000 feet would give only 3,200 c. p. hours for $1. That is to say, the ratio is that of 11,200 as against 3,200 in favor of electric light.

As Chief Engineer Baird points out, the gas output might be doubled per unit of gas by using the Welsbach burner; but even this it will be seen would not bring gas up to the economy of the electric light; while he remarks that the cost of replacing the mantles would probably be half the price of the gas saved.

ELECTRIC MOTORS IN FACTORIES.

AT a recent meeting of the American Society of Mechanical Engineers, Prof. D. C. Jackson read a paper on electrical power equipment for general factory purposes, in which he discusses the various cases which arise in practice, and gives the results of the use of power transmission in ten typical plants employing each over 1,000 h. p. in capacity of electric motors, as well as in a similar number using from 100 to 500 h. p. He sums up by saying that in constructing new manufacturing plants the extra first cost of a complete system of electrical transmission is negligibly small, except under exceptional circumstances, compared with the actual saving effected by this means, when its advantages are properly utilized. In certain industries the advantages of electrical transmission outweigh the first cost of making a change from mechanical to electrical transmission in established plants, while in many plants where these conditions would not commonly exist the arrangement of buildings or the growth of the plant is frequently of such a character, with reference to the prime power plant, as to place electrical transmission upon an advantageous footing, either as an auxiliary to the main transmission or as a rival to existing mechanical transmission. Perhaps no better argument in favor of electrical transmission could have been brought forward by Prof. Jackson than his quoting of a letter received in reply to his inquiry from the owner of an establishment which had introduced electrical transmission. The reply reads: "In these days of active competition we do not feel it is wise to make public the savings or advantages derived by introducing various economies." Prof. Jackson says he has not been able to decide whether the experience of the writer of the letter was favorable or unfavorable to electrical transmission, but we venture to believe that the electric motor was found to be a paying investment, and that the experience of the writer of the letter agreed with the experience of that of the majority of Prof. Jackson's correspondents, which was in favor of the electrical plant to a most marked degree.

THE INDEPENDENT TELEPHONE CONVENTION AT DETROIT.

THE meeting of the "independent" telephone companies, held at Detroit this week, was one of unusual significance and importance, justifying us, we think, in the delay of one day in the publication of this issue of The Electrical Engineer in order that we may present the results with promptness to our readers, many of whom, in every field, have been watching the development of the telephone situation. We present elsewhere in this issue a copious report of the work of the convention in such form that anyone can reach his own conclusion as to what is likely to be the outcome of the whole matter. A few remarks consequent upon observations made on the spot, will not, however, be out of place, as they may assist in getting at the significance of what was said and done.

It is, to begin with, surprising that the elements of opposition to the Bell regime should so rapidly have come into union and be able now to present a combined front of active workers. There are, it is true, nominally 1,200 of these independent concerns, some of considerable magnitude, with an estimated total of 150,000 instruments and 2,500 miles of toll line; but many of these companies are very small and many others are not yet in operation. Still, that the number should already be so large is striking, and if it should double in the year, the fact would not be remarkable. Some of the new plants, as at St. Louis, Saginaw and other cities will vie in proportions with the best of the "old line" Bell organizations. Now, one of the facts holding this industry together is the effective cement of a common cause against the American Bell system, and, it would seem, a common fear of both open and insidious attack from that very formidable quarter. On the floor of the convention itself the historic warning that if they did not hang together they might all hang separately was caught up with quick intuition of its deep meaning. In spite of the most violent extremes of opinion on moot points, there was shown a general keen desire and intention to cohere as closely as possible for common measures of defense and offense alike.

The main differences of opinion arose, as will be noted from our report, upon the fundamental questions of representation and taxation. There was, as there always has been in associations of local companies, a strong desire to keep out the "parent company" influence and to prevent it from control, especially with bunches of proxies from owned plants; but the impossibility of barring out manufacturers as individual operators of exchanges was evident, for whatever be the conditions, the ownership of the plant will count in some way and will direct the casting of its vote as a local company. Another incidental question was that of State Association membership, but this is neatly met by the Federal Executive Committee with two representatives from each interested State. Upon the matter of taxation the fight was hot, and was forced particularly by the larger exchanges, such as Detroit, whose dues under the new constitution would obviously run up into thousands of dollars, and be a fund that it would much rather spend for itself in case of litigation on patents. Here again, however, the necessity of standing together came out, for mutual protection is the first necessity of the hour for these intruders on the jealously-guarded Bell domain; and there is no doubt that the membership will be large enough to afford a handsome fund as a basis for work of the defensive kind. It seems to us that there was a little too much crying "Wolf!" in the convention, or at least, too much publicity given to their dread on the part of many members that the opponent might soon and suddenly pounce down on the fold. One knotty problem hinted at but not discussed was how to espouse the cause of companies not joining the association. It might not be quite safe to leave them to their own devices.

Political work was the chief care of the convention, rather than the strictly commercial and technical aspects of the subject; and there were certainly several skillful politicians on the floor. In fact there were, it might be said, three groups of men pretty clearly defined: the manufacturers building the new exchanges and often deeply interested in their financial success; the outside investor who believes in the new business and the greater popularity and profit of the telephone; and the plain politician, who sees in the situation and the genuine feeling on the part of the public in many places against the Bell Company, a chance for deals and legislation that has not hitherto presented itself. On the whole, the quality of the attendance was very high. It is true that one operator of a modest exchange is at home a "director of funeral ceremonies" who had come to help bury arrogant Cæsar, but his associates are, many of them, men of weight, wealth, reputation and influence of the highest grade, and their power is going to be felt.

The events of the year that must elapse before the next association meeting are sure to be full of interest and excitement. Where will the Bell Company strike and how? If ever there were a set of men spoiling for a fight, they will be those in the association with a fund of twenty or thirty thousand dollars behind them to start with; and probably they could not ask an easier object of attack than the Berliner patent, whose existence offends the moral sense of the nation. But while the Bell Company may be vulnerable, it has rights and legitimate patents, and a great business organization built up through long years that can only be equaled by the same amount of study and investment. Here, perhaps, may lie the Bell strength, after all, hotly as the patents it owns may necessarily be pushed as controlling factors. Some of us remember the hurrah days of the Bell beginnings, when with generally low rates it seemed as though income alone had to be thought about. Then came the trying times of system reconstruction, and the rates began to go up. While the Bell rates of late years have often reached the one extreme, those of many of the new independent companies are ruinously low and cannot last. In fact, it may be found that in large numbers of cases, the Bell rates governing before this fight began were such as the conditions of the art fairly dictate; and if this be so, some opposition companies must even in a short time come up to them or be wiped out by their own burden of expense and debt. For the public, meantime, there seems assured a period of cheap universal telephony such as it has never known before.

BEAUTIES OF THE THIRD RAIL.

THE discussions upon the third rail trolley system have been limited of late to the economic advantages as compared with steam locomotive methods and much has been said about the relative chances of survival of competing trolley and steam roads. The "Springfield Republican" comes forward, however, with a formidable tirade against the steam locomotive, and makes a strong case for the third rail on the æsthetic side. It speaks of the roadbed as a sahara of gravel and cinders. It describes the engines as cyclopean monsters belching masses of smoke and grime. It asserts that each road has its attendant black belt of desolation; that the houses near the track are spoiled; and that the stations are the "foulest and dingiest places known to man." The traveler for a hundred miles is delivered at his journey's end in the condition of a chimney sweep and ready for a Turkish bath.

All this is very savage and severe, but it is doubtless true that the third rail, dispensing also as it does with poles and overhanging wires, has its advantages in the shape of superior comfort, cleanliness and beauty. The steam roads are hardly likely to even things up by adopting the new plan of the Camden and Atlantic R. R., which lays the dust by deluging its track with heavy oil of low cost! The "Springfield Republican" wants grass to be grown all over the trolley track, a thing which is already done, and it believes that in various ways the third rail will make life more endurable for the passenger. "The railroads have an advantage in point of speed," it says, but it is not wise in thinking that the trolley cars "apparently never can approach the same rate." Indeed there is no good reason why, even now, for all ordinary travel, they should not go faster than the average locomotive.

LARGE CENTRAL POWER PLANTS.

IT was foreseen that the effects of the great Niagara power plant would not be wholly confined within the local limits of that borough, nor even of a zone of twenty-five or fifty miles, but we hardly expected to see so early a fruition of the main idea, if we may use the phrase, for which Niagara stands. With only a small part of the ultimate capacity of its works in operation the Niagara Power Company, already finds its example emulated, or in progress of emulation, in various quarters. But, curious to say, several of the projects called into life are not based on favorable water powers, but on cheap coal. We have already noted the inauguration of a scheme of this nature at Leavenworth, Kan., and now we observe that a similar plant is advocated by Mr. L. B. Stillwell for supplying power to Pittsburg, in a paper read before the Engineers' Society of Western Pennsylvania. As a matter of fact the society is now busily engaged in gathering statistics as to the cost of power in Pittsburg at the present time, and has submitted a series of questions to power users to enable it to obtain the desired information. The plan, of course, is to build a large central steam power plant and to distribute power electrically and thus displace the numerous steam engines in and about Pittsburg. There seems to us to be nothing chimerical in this scheme, and we trust the society having the work in charge will proceed in the collection and tabulation of the data in order to determine whether the plan may be practically carried out.

(Continued from page 717.)

vantage in various ways, although a failure. It had kept the Bell Company at bay for some time, giving the independent companies time to organize a nd get on their feet. It had allowed the independent movement, supported by the people, to get fairly started. It had also allowed important evidence to be secured of the utmost use by its value and significance to those who might desire to defend themselves against infringement suits. Witnesses had been examined in that case whose testimony was now on record so that they could never go away from it, and that evidence would be of the utmost value in the hands of those defending any such suits under the patent.

As to what would happen, it was impossible for himself or any one to say. He had confidence in justice and truth and in the final victory of that which ought to be. He knew a great deal about the patent, and without any sort of question it was the most unblushing, bare-faced, thinnest, inexcusable, abominable fraud that ever received the sanction of Government. (Tremendous applause.) It had not one single redeeming feature about it. It had not given the world one single idea about the telephone. It had not advanced the progress of the world one minute. The telephone art was to-day just exactly where it would have been if Mr. Berliner had never been born. There was not underlying the patent one single particle of merit. Nobody had ever said there was, not even the counsel for the Bell company. No court had ever decided that it had any merit. The only court that had ever said a word about its intrinsic merit and its legal validity was the U. S. Circuit Court for the District of Massachusetts, and that had decided it was void. The Supreme Court of the United States had not undertaken to pronounce on the validity of the patent. It went no further than to say that for the particular reason of alleged fraud in its issuance, the court saw no reason to interfere, and would not. Everything else was left out of consideration.

That the patent application had been nursed in the Patent Office from year to year for nine years, on purpose to extend its life, was a thing which he believed nobody who had ever looked into the record doubted for a moment, and neither the U. S. Supreme Court nor the Circuit Court of Appeals had decided that that was not so. No one had ever said so except the counsel of the Bell company in their argument, which they immediately knocked out by saying it was no matter, and had no effect on the case if they did delay.

Judge Taylor said he was unable to believe that when they got at it, the courts of the United States would sustain and enforce this patent for the long period of years which it had nominally to run. Such a monstrous wrong upon the people, he did not believe possible, although he did not want them to take his word for it or anything at all. He was excusing and explaining his presence there, and what he had said to people who had asked him questions. A good acquaintance of his, interested in independent telephony, who had recently bought some telephones, had asked his advice about putting them in. He had told him to have faith and courage and to go right ahead and put them in and he would come out all right.

Judge Taylor said that he regarded this talk as probably outside the proper business of the convention. But he had alluded to it simply because it was in their mind, because it had been talked about, because there had been misunderstandings in regard to it, and because it was desirable they should have the truth—at least, as he understood it.

They were met together as a representative commercial convention of a great business, and they had done wisely in coming together and organizing. It wás the American instinct of self-government to do so, and when several hundred men embarked in a business of a given character got together, they quickly adopted laws and elected officers and set up a system of government among themselves. They could now exchange ideas, experience and facts, and disseminate to each other information needed in the conduct of the business. It was to the interest of every one of the local exchanges to be represented, and there were none of them with antagonizing interests or rivalry. The subscriber to the independent system in Detroit would use that in Fort Wayne, as he did, and it would do the subscribers good to feel that they had their mouth to that kind of a hole. (Laughter.) The telephone business, moreover, was one in respect to which very much had still to be learned, in the handling of the staff, the traffic, the lines and other details, and that alone was enough to justify the existence of such an association.

In conclusion Judge Taylor emphasized the influence they might have on legislation and on the improvement of the patent law and system, if they would take the matter in hand, and urged them to proceed with their great work of popularizing the telephone everywhere, and thus of lengthening life, as benefactors to the whole American people. (Great applause.)

JUDGE THOMAS, of Chillicothe, O., president of the convention, said:

It is an honor to preside over the temporary deliberations of so large and intelligent a body of men, gathered together from all quarters of the greatest country in the world. We come together to promote the interests of a just cause and on behalf of the people of this great nation. We know no party, no creed, no State, no North, no South, no East, no West; but the motive that brings us together is pure, is just and right, and is as broad as the expanse of our great territory, having one common object, and that object being pure and right—we have no room for disagreement and I sincerely hope that during the whole course of our deliberations we will keep this fact clearly in mind. While we may not all agree as to details, we hope that long and tedious discussions of minor matters will be obviated so that the work of the convention may proceed with due speed and an organization be formed before we adjourn, that will make still stronger the confidence of the people in this movement. There will be no room for obstinacy here, there will be no demand in this convention for motives either selfish or spiteful. If any came bringing to this meeting motives other than to help take up this great work with zeal and unselfishness, dispel those motives at once and place yourself in the ranks of the great army which will win in a short time the greatest commercial victory that this country has ever seen.

We are told in some of our journals that the telephone business is and must of necessity be a "natural monopoly." We answer that by saying that the people of this free country abhor either a natural or an artificial monopoly, as does Nature a vacuum. It is strange that the American Bell Telephone Company has spent so many millions of dollars in trying to maintain a monopoly when Nature has been so kind as to give it natural protection. If these journals are right, old Mother Nature must have been away from home the past two years and has forgotten to instruct the boys to look after this natural monopoly in her absence.

We are told again in these same journals that the independent telephone movement has been a failure and they cite us to a few instances where persons or corporations without capital have been so unfortunate as to have executions levied upon their property and the same offered for sale by the sheriff. Of course one would infer from these paid articles that this is the only business where this state of affairs has existed. They apparently forget that more than 1,000 independent telephone companies are to-day doing a successful and profitable business. It seems to one after studying the situation and watching closely the movements of the American Bell Telephone Company and its lessees that those companies have not fully comprehended the vast territory of this country. When we stop to consider that up to two years ago there were only comparatively a few people in the United States who felt themselves able to pay for telephones on account of the exorbitant charges made by these companies, and, at the same time, think of the progress that has been made in the telephone enterprise in other countries, it seems that they have taken a very narrow view of the subject.

There is no country in the world where there is such a great demand for rapid communication as in the United States. Our people are quick to act, always energetic when engaged in any business, and have not the patience to await slow communications. There is always a demand for faster mail trains—there is always demand for quicker telegraph and more rapid telephone communications, and since it has been demonstrated that the price of the telephone can be reduced to a point where the common people can afford not only to use them in their business affairs, but also in their domestic affairs, the desire for quick communications has been increased to a very great extent. In fact, the people demand this as their right, and any action of the American Bell Telephone Company under a pretense of still owning fundamental patents will be met with a very decided opposition by the great masses of the people.

The people have looked forward to the time when, under our patent laws, this invention would be open to fair competition. The people fully believe that this time has arrived. We have been taught to believe that our Government, under our patent laws, protected an invention for a period of seventeen years and no more. We know that the microphone has been in use more than that time and that the owners of patents upon that invention have had their full protection under the law. Men all over the country who have studied the patent situation know that the rights of the American Bell Telephone Company under their fundamental patents have expired. We claim now the right under our Government to use those inventions for the public good.

Why should these rights be denied us? Or why should the capital invested by men who are well aware of these rights be jeopardized and their business threatened by a company whose rights have long since expired to hold a monopoly under those patents? Why should we longer be annoyed by notices and threats made in newspapers to refrain from using this invention. We are unable to explain to ourselves why this state of affairs should go on, and knowing that the great masses of the people are in harmony with this movement we meet to-day for the mutual purpose of forming an organization for the mutual protection of those who invested their money in this enterprise as well as the protection of the rights of the great masses of the people in this country.

If we are wrong as to our understanding of the law of this country, the American Bell Telephone Company still has a right under the Berliner patent of 1891 to a monopoly of the microphone, and we will abide the decision of the courts of this country; if we are right we demand as a matter of right that we be allowed to enjoy the privilege of the use of this invention without further annoyance. I have never been able to explain why a great corporation should be so short sighted as to insist upon something that neither reason nor law guarantees them in trying to hold.

It would be far better for them to concede what might be a right than through even a technicality of the law to attempt to rob the people of that which in reality and fairness belongs to them. There is plenty of room in the United States for every manufacturer of telephones, for every company that is operating a telephone system or toll line, and if we were all as industrious for the next twenty-five years as the independent telephone people have been the past two years, our territory would not then be half covered. It would be a long time before this country can say that there is one telephone in operation for every eleven inhabitants within municipal districts. Holland can now boast that in that country the telephone business has reached that point. How has it been brought about? Simply from the fact that since the invention of the telephone prices have been moderate.

If we look into the telephone business in a few other countries certainly we will find every encouragement to proceed with renewed energy to build up a complete system in this country. The history of the independent telephone movement in the countries of Norway and Sweden certainly furnishes great encouragement to those who have undertaken this enterprise in the United States. We are told that in these countries there is in operation one telephone for every seventeen inhabitants within municipal districts. The Bell Telephone Company was the first to enter the field in these countries. They followed their policy of high prices and independent management, heeding not the demand or the desire of the people, and as the result of that policy were enabled to place only a few telephones in operation. The opposition telephone company came into being, established an exchange in the city of Stockholm at moderate prices and adopted a policy of accommodating their patrons. In a short time the independent company was operating nearly five times as many telephones as were operated by the Bell Telephone Company at the time they entered the field. This was followed in other cities in these countries, and in a short time the Bell Telephone Company was compelled to retire from the city of Stockholm, sold its property to the independent company for what it could obtain, and the same result followed in the other important cities of the countries, until to-day the telephone system of these two countries is owned and in the control of the people who in no wise are connected with the Bell Telephone Company. This will certainly be encouragement enough, and it is safe to predict that unless the Bell Telephone Company changes its policy, the same result will follow in this country from the fact that there are hundreds of cities throughout the United States where the lessees of the Bell Telephone Company do not receive enough income to pay their employés.

It is a remarkable fact that for more than two years the independent telephone exchanges in hundreds of cities throughout this country have continually increased their patrons, when the lessees of the Bell Telephone Company were furnishing telephones free to anyone who would allow them to place one in his residence or place of business. This is certainly a true indication of the feeling of the people. I have often wondered if the American Bell Telephone Company fully realized this state of affairs. If they do, it certainly affords them food for thought. There is always some reason when a man will pay for something that he has an opportunity to receive for nothing. There has been more than $20,000,000 invested in the independent telephone enterprise in this country, but a greater capital stock than all this money is the fact that we have the sympathy of the people and have in every locality where a successfully managed independent telephone exchange exists a local influence which can never be taken from us so long as we do our duty, give good service and subserve to the wishes of the citizens.

It was predicted by every important journal in this country in the early days of the telephone that it would succeed and do away with the telegraph. The Western Union Telegraph Company must have believed that this prediction would come true, for we find them in the great lead to get control of patents. It seems that they risked their fortunes with Edison while Bell, Blake and Berliner were gathered in by the American Bell Telephone Company. Then after a brief struggle for the telephone field, we find an agreement was made between these two great corporations in which it was provided to the satisfactory arrangement of both that one should retire from the telephone field and should receive the consideration of a few million dollars. So the prophets' prediction failed. The telegraph business continued as before. The telephone was conducted so quietly that the people never dreamed of the immense fortunes which were being accumulated under these patents and under these arrangements until their attention was called to it by this independent telephone war. We believe that the contract made between the Western Union Telegraph Company and the American Bell Telephone Company has done more to retard the universal progress of quick communication than anything that has ever happened since the invention of the telegraph and the telephone. So soon as this battle is over the people will be surprised at the growth which rapid communication will make. Messages will be transmitted over telephone wires and recorded at the receiving end, delivered to the party addressed, and the answer returned, recorded and delivered without causing people to wait for lines and to get parties to the 'phone. Time will be saved, more words will be transmitted at the same expense and the commercial world will feel the advantage of this form of communication.

It will not be long until the telephone is a very essential feature of our Post Office Department. So much letter writing is burdensome, and with all the advantages of our fast trains we are impatient with this manner of communication. We would be better pleased and time would be saved if for a reasonable sum of money we could talk to those with whom we have business or with whom we desire to communicate. Taking then the vast territory, our great population of 70,000,000 of people, this great and growing demand for quick communication, and the probability that it may in the near future be adopted as the greatest department of our postal system, the field is so great that it seems folly for one company or one corporation to stop progress by giving time to quarreling, contention and litigation. There is still room for more to enter this great field, and one need have no fear of competition in the next half century.

If, however, there is not in this view of the case, sufficient to exact peace, then let the war go on. The American Bell Telephone Company will find that this battle is their Waterloo. They will find that others have been thinking while its officers have been scheming to make money. They will find, too, that our courts will uphold the law if brought under the state of facts proven. They will find, also, that it will not be trying the suit of the Government for the cancellation of a patent. They will find that evidence exists which, when the proper time comes, will be shown to the courts, and they will find that the courts will decide as the judges presiding over them are bound to do under the oath according to the law and the facts. And while they boast of their victories and say nothing of their numerous defeats recently; and while they boast of their great technical lawyers, of their many millions of money and their numerous expert witnesses which have been retained, still they will find that in this great country there are others equally as learned who are ready and willing to espouse the cause of this movement, knowing that a great victory will reward their efforts. It remains then for the American Bell Telephone Company to say what policy it will pursue, but it should understand whether in peace or war, we will meet them, and in peace will greet them, in war will surely defeat them.

The following committee of five on credentials was then appointed: Alex. I. McLeod, Detroit, chairman; W. L. Crisman, Cedar Rapids, Ia.; E. H. Andress, Lafayette, Ind.; Peter E. Blow, Knoxville, Tenn.; and William Hoyle, Cambridge, O., and a recess was taken while the committee prepared its report.

A hot discussion started over the report of the Committee on Credentials. Briefly, the committee had decided that four delegates from Pennsylvania, West Virginia and Eastern Ohio, representing the twenty-seven exchanges in the Inter-state-State Telephone Exchange Association could not vote for any other than the individual companies they represented, although they had been elected to vote as proxies for the other twenty-three companies. The same decision affected five delegates from Indiana who had been elected to cast the votes of thirty-eight telephone exchanges in that State. The committee decided they were entitled to only their five individual votees.

That started a debate that continued for nearly an hour, all the delegates from Pennsylvania, headed by Mr. A. Dively, and those from Indiana making energetic protests at what they considered deprived over fifty companies from being represented in the convention. A. B. Coon, of Marengo, Ill., moved an amendment to the committee's report that would permit the nine delegates from Pennsylvania, Ohio, Indiana and West Virginia to vote for all the telephone companies from which they had credentials. James Jamison, of Newcastle, Pa., supported the amendment. He stated that at a meeting of the Interstate Association, of which he is a member, to elect delegates to the present convention, it was understood that only two or three delegates would be allowed. Accordingly no more were sent. Another delegate from Pennsylvania spoke in favor of the amendment, declaring that the question ought to be settled at once, so that all accredited delegates could participate in the proceedings of the temporary organization.

Alex. I. McLeod, of the Detroit Telephone Company, who was chairman of the Credentials Committee, made a very hot speech against the proposed amendment.

"There can be no legal proxy in this convention during its preliminary organization," asserted S. A. Harper, of Madison, Wis. "There is nothing as yet authorizing me to represent anyone. No permanent organization has been formed, no constitution has been adopted."

A motion to have laid on the table the report of the Committee on Credentials was lost and then the convention adopted the report.

After adjournment, A. V. Dively, of Pennsylvania, and E. H. Andress, of Lafayette, Ind., and others spoke bitterly against the action of the convention in refusing to allow the few delegates from each State to represent all the independent telephone companies in their State which provided them with credentials. They threatened to withdraw from the convention, and some intimated that Mr. McLeod only fought the amendment because he wanted to get support for himself as secretary of the permanent national organization. This, however, Mr. McLeod emphatically denied.

"The three delegates here will withdraw from the convention if we are not allowed to represent all the independent telephone companies that belong to the Pennsylvania association," said Delegate A. V. Dively, of Pittsburg. "Having been instructed to represent our entire association, I cannot isolate any one company and represent it. We propose to fight this thing to a finish. I understand a slate has been fixed up which includes A. I. McLeod for secretary of the permanent organization."

FIRST DAY, EVENING SESSION.

The Executive Committee through its temporary chairman, which had been in session nearly all day, reported a constitution and by-laws. Secretary Critchfield read the report. The name of the association was given as "The Independent Telephone Association of the United States of America." The association's object is to mutually protect the interests of independent telephone companies; also to bring about a complete system of inter-municipal independent telephone exchanges. The membership fee was to be $10 and a delegate to the association shall be a member of any independent telephone exchange. Each exchange should pay 50 cents per subscriber and 25 cents per mile of toll line. Each delegate shall be entitled to one vote only, barring those representative concerns engaged in the manufacture of telephones or telephonic apparatus for sale in the general market. There shall be an advisory board to direct the finances of the association, to call special meetings, to levy assessments when necessary, to contract for the association and to generally supervise the operations of the organization. When the executive committee is not in session the advisory board shall direct the officers of the association. The salary of the president of the association shall not exceed $2,500 a year, that of the secretary $1,000, and that of the treasurer $700, all to be allowed actual expenses on presentation of proper vouchers to the advisory board. Ten members of the executive committee shall constitute a quorum, and a majority of the members of the advisory board.

A motion was made that all those who had not submitted credentials to the committee do so and that those who were not provided with them should be entitled to vote in the convention. This was done and the Credentials Committee retired to an ante-room with the delegates whose credentials had not been passed upon. The committee reported in favor of admitting twenty-two more delegates, and their report was adopted.

On motion of Mr. Alex. I. McLeod, it was decided to adopt each section seriatim where there was no objection. Delegate I. A. Lumpkin, of Mattoon, Ill., suggested that a representative of the Bell Company, or someone else almost as objectionable, might be present and moved that a roll call be taken. It was found that five exchanges were represented by two men each, and as only one could vote, the extra representatives were excluded from active participation in the proceedings of the convention. Similar disposition was made of two extra representatives of manufacturing concerns.

The article of the constitution providing for the levying of an assessment not to exceed 50 cents for each independent telephone in actual use and another of 25 cents a mile for each toll line was considered. Delegate Holmes moved an amendment that each telephone be assessed not to exceed 10 cents and each toll line not to exceed 5 cents.

Mr. Critchfield, of the Executive Committee having the report of constitution in charge, strenuously objected to the proposed reduction in assessments. He insisted that it might be necessary to raise from $150,000 to $200,000 to fight the association's common enemy, and deplored the manifestations of dissension among the delegates at both the afternoon and evening sessions. Ex-Judge Hatch, of the Detroit Telephone Co., declared the recommendations of the committee for assessments were exceedingly extravagant.

MR. W. L. HOLMES of Detroit, rose and said: "The Detroit Telephone Company is not prepared to enter any association that contemplates a law suit. We do not fear any litigation with our own apparatus now in operation. We have been running two years and the Bell Company have not made the slightest intimation of any kind as to infringement."

At the suggestion of Chairman Thomas, a motion was made that the convention go into executive session for the purpose of excluding the reporters, but it was voted down. A motion to lay on the table was lost, as also was a motion to fix the amount at 25 cents. This left the assessment at 50 cents on each independent telephone concern, and 25 cents a mile for each toll line, which was according to the committee's report.

Mr. Critchfield estimated the number of independent telephones in use at 150,000 to 175,000, and the amount of toll line at 2,500 miles. Much toll line was carrying business free of extra charge to the independent subscriber.

MR. H. A. TAYLOR, of Madison, Wis., manufacturing telephones and owning telephone exchanges, made a strong plea for the granting to manufacturers the right to vote on all questions in the conventions. Secretary Critchfield, of the committee, said that the provision excluding manufacturers from participation in the association's proceedings was recommended because they were considered provokers of dissension. He admitted in answer to a question from Charles Flowers, of this city, that in cases where one man owned nine-tenths of the manufacturing plant of a telephone company and another man a one-tenth interest in the exchange, the latter would be entitled to represent the company and vote in conventions of the association. The committee's report excluding manufacturers was then adopted.

Article V. was adopted with little debate. It provides for an executive committee of two members from each State.

Articles VI. and VII. defining the duties and salaries of the various officers were adopted, but with objections as to the $2,500 salary voted the president. An Indiana delegate wanted it reduced to $1,000, urging that the office was honorary, times were hard, and the independent telephones were in a critical position. Other amendments were to cut the salary to $1,500, and a third wanted the question of its amount left to the executive committee. All the amendments were voted down by a storm of noes, and the president's salary stood at $2,500. The salary of the secretary was left to the discretion of the executive committee, not to exceed $1,000 a year, and a suitable allowance for expenses, also to be fixed by the executive committee. One man wanted the salary fixed at $1,500, the secretary to also assume the duties of treasurer. Several delegates objected to joining the two offices, saying it was a temptation to a man's honesty. The amendment was defeated by a unanimous vote, and the section was adopted. The treasurer's salary was fixed at $750, a motion to reduce it to $500 being lost.

The remaining article of the constitution defined the duties of the executive committee and advisory board, and the qualifications of members of the association. One clause of Article VIII. shut out manufacturers and dealers in telephone apparatus from active membership. They are entitled to honorary recognition only. There was more objection to this, one delegation holding that it was assessing taxation without granting representation, as manufacturers and dealers were supposed to contribute the funds of the association. He wanted this clause referred back to the executive committee and it was so ordered by a vote of 48 to 31, the committee to report on Wednesday morning at 9 o'clock.

A motion made to adjourn when 12 o'clock struck was defeated, on a statement that ten minutes more would dispose of the constitution, and the adoption of the remainder of its provisions was proceeded with.

At 12:20 o'clock a. m. the convention adjourned until 9 o'clock Wednesday.

Mr. Peter E. Blow, Knoxville, Tenn., stated as the convention rose, that if the constitution was adopted as a whole as read the Tennessee delegation would withdraw from the association.

SECOND DAY.—MORNING SESSION.

JUDGE THOMAS called for the report of the committee on Article 8. After discussion, Mr. Critchfield said the committee had decided to recommend one extra vote for every 500 telephones or the major fraction of such number of telephones.

MR. RYAN suggested that a certain proportion of toll line represent so many telephones—one mile equal to one instrument.

MR. W. C. STERLING, JR., moved as a substitute that each exchange be entitled to one vote for each 100 telephones in use, no exchange to have less than one vote. Substitute was lost.

JUDGE HATCH brought up the question of manufacturers representing exchanges in any way. This referred to Article 3, changing it to allow manufacturers in if they had the exchange qualification.

MR. BLOW supported the motion as to actual voting, but not as to proxies for exchanges in which such manufacturer had no stock interest. He cited the case of a man who has built three exchanges, but had bought some timber land for his pins, etc., and is now shipping them all over the country. He should not be excluded because he was a manufacturer.

JUDGE HATCH withdrew his first motion and moved to refer back to the committee with instructions to remove all disqualifications against manufacturers if they had the regular exchange qualifications.

MR. CRITCHFIELD said that not a single manufacturer had been found who was not also interested in one or more exchanges.

MR. HARPER wanted the limitation that a manufacturer should have anyhow but one vote. That would meet the fear of a manufacturer swamping them with his proxies.

MR. DOUGHERTY pointed out that this movement would not limit the manufacturer, who would be represented by his own appointees even if he had only one vote for himself.

A motion to lay on the table was carried.

Articles 3 and 8 were then referred back to the committee for immediate action.

Article 3 was reported back as changed to limit to $10 the only present payment.

Article 8 was amended by striking out the objectionable features as to exchanges being represented by manufacturers, who could now speak for their own exchanges. The disqualification was thus removed.

A motion was made to adopt the constitution as a whole.

MR. HOLMES, representing the Detroit Telephone Co., said there were many objections among his associates to the constitution as it stood as a whole. They objected to joining a body organized for litigation. They believed in a commercial association co-operating to extend toll lines and to secure legislation favoring their purposes. The independent companies were popular and could get the legislation needed. What was really wanted was legislation, not litigation. Mr. Holmes objected strongly also to the charges per instrument and per toll mile and to the heavy salaries. The proposed constitution was on the wrong path. It was foolish and suicidal. They should not give out, moreover, that they feared or expected litigation. If sued, they could attend to that when it came. The Grand Rapids exchange had met the agents of the Bell Company three times on litigation and had downed them.

MR. CRITCHFIELD remarked that his Detroit friends had laid off 200 men right after the Berliner decision. What did they fear?

MR. HOLMES denied any stoppage or restriction of work.

MR. C. M. ZION reminded them of the old revolutionary saying that if they did not hang together they would hang separately.

The question was asked but not answered as to what would be done if the Bell Company sued a company not in the association.

The constitution was then carried by a large majority vote.

MR. D. A. REYNOLDS then urged that the membership fee be collected before a resolution to name and elect the executive committee of the new association or its advisory board.

MR. HARPER insisted that they must now act under the new constitution, the temporary organization having done its work.

MR. VESEY was elected as temporary secretary of the new organisation.

MR. McLEOD moved that the States get together at once during a recess of twenty minutes and choose two members each for the executive committee. Agreed.

On resumption a rising vote of thanks was given to the temporary Executive Committee for its work.

An Executive Committee was then formed based on two members for each State represented in the convention. About twenty-one States were put in nomination, and others will be added from time to time.

MR. CRITCHFIELD moved the election of these gentlemen.—Agreed.

It was agreed that the Executive Committee meet on the boat that afternoon.

Adjourned till 7 p. m. Wednesday evening.

WEDNESDAY.—EVENING SESSION.

The Executive Committee elected at the morning session made its report.

Mr. Harper made the report. Mr. Savidge had been elected president; himself secretary, and as seven members of the Advisory Board had chosen Messrs. Savidge Critchfield, Dougherty, Marshall, Duncan, Miller and Higgins.

JUDGE THOMAS said that the manufacturers had met and had appointed a committee to confer next week with the Advisory Board.

The meeting then proceeded to the election of officers.

JUDGE THOMAS was elected president by acclamation and returned thanks briefly, stating how deeply he felt the responsibility at this vital moment. The work accomplished and closing in harmony meant victory for the independent telephone cause in the United States. He closed by appealing to them all for active co-operation.

The following officers were then elected:

First Vice-President, H. C. Young.
Second Vice-President, E. K. Himes.
Third Vice-President, T. Fricker.
Secretary, W. J. Vesey.
First Assistant Secretary, Z. W. Beers.
Second Assistant Secretary, D. C. Dow.
Treasurer, L. A. Carr.

The other nominees for the treasurership being D. A. Mossman and F. W. Hoyt.

A very hearty vote of thanks was given to the Detroit Telephone Company for their lavish hospitality.

We give below the complete text of the constitution as adopted:

ARTICLE I.—NAME.

The name of this organization shall be the Independent Telephone Association of the United States of America.

ARTICLE II.—OBJECT.

The objects of this association shall be:

1. The protection of all independent telephone interests of common concern to the members of the association.
2. The protection of subscribers to telephones and apparatus operated by members of this association.
3. The bringing about a reasonable charge for tolls and the rental of telephones, so that the telephone may be within the reach of the masses of people.
4. The bringing about a complete system of intermunicipal communication and long-distance trunk lines.

ARTICLE III.—MEMBERSHIP.

Any corporation, partnership, or individual engaged in the operation of an independent telephone exchange, toll line, or system, may become a member of this association by complying with the following conditions:

1. The payment of a membership fee of $10 and the first assessment levied as hereinafter provided; provided, however, that the payment of the membership fee and signing the constitution only shall entitle the member so paying to vote in the election of officers, upon the adoption of this constitution, but not thereafter.
2. The payment, from time to time, of such further assessments as the association, through its proper committee, may levy, not to exceed in any one year fifty cents for each telephone in use by any exchange or toll line company, and fifty cents per mile of pole lines, carrying a wire or wires, over which paid messages are transmitted.
3. Any corporation, partnership or individual engaged in the manufacture or sale of apparatus or materials used in the construction, operation or maintenance of an independent telephone exchange, toll line or system, may be called upon by the Advisory Board for such voluntary contribution as in the judgment of said board may be equitable and necessary, and upon payment of the same, shall, at the option of the contributing party, be made an honorary member of the association. The secretary shall make monthly report to the president, the Advisory Board and the Executive Committee, and an annual report to the association, of the persons, firms, or corporations entitled to honorary membership under the provisions of this article, and the amount contributed by each. The receipt of the secretary shall be the certificate of such membership, but honorary members shall have no voice in transacting the business of the association, as a matter of right.
4. By subscribing to the constitution and by-laws of the association.

ARTICLE IV.—OFFICERS.

The officers of this association shall be a president, three vice-presidents, a secretary, two assistant secretaries, a treasurer, and an Advisory Board, consisting of nine members, two of whom shall be the president and secretary of this association, together with seven members who shall be selected by the Executive Committee. The president and secretary of the association shall be ex-officio chairman and secretary of the Advisory Board and Executive Committee, respectively.

ARTICLE V.—COMMITTEES.

The association shall elect an Executive Committee, which shall consist of two members from each State; each State, through its delegates, to suggest the names of the members of said committee to represent such State. Should any State be without representation in the convention, the convention shall then select two members from such State, who shall act until the vacancy shall be properly filled under this article. The Executive Committee shall, with the consent of the Advisory Board, select such sub-committees as it deems expedient and necessary, and shall fully empower such sub-committees to carry out the objects for which they were created.

ARTICLE VI.—ELECTION OF OFFICERS.

The officers herein provided for, except the Advisory Board, shall be elected as provided in Article 14 hereof, on the adoption of this constitution, and thereafter at the regular annual meeting of the association, to be held in June of each year. The time and place of holding such annual meeting shall be fixed by the Executive Committee. The officers so elected shall serve until the next succeeding annual meeting, or until their successors are elected and qualified.

ARTICLE VII.—DUTIES OF OFFICERS.

1. The president shall preside at all meetings of the association, Advisory Board and Executive Committee. He shall, under the direction of the Advisory Board, conduct a bureau of information for the benefit of members of this association, and shall, with the assistance of the Advisory Board, collect all data and information relating to the welfare and promotion of independent telephone interests. He shall procure facts and evidence tending to the protection and promotion of such interests. He shall have power to call to his assistance for consultation the officers, committees and members of this association. He shall approve and countersign all orders drawn on the treasurer of the said association; shall approve and sign all contracts and bonds made by this association; shall approve all bonds made to this association, and be custodian of the same, and shall perform such other duties as naturally devolve upon his office. He shall receive such salary, not to exceed $2,500 per year, as the Executive Committee shall fix; shall have an allowance for expenses, to be paid upon approval of the Advisory Board on presentation of properly executed vouchers. His salary shall be paid at the end of each quarter by draft made on the treasurer. He shall give bond in such sum as the Executive Committee may require, with such security as may be approved by the Advisory Board.

2. VICE-PRESIDENTS.—The vice-presidents shall rank first, second and third, according to the choice of the association, to be designated at the time of their election, and shall, in their order, perform the duties of the president so far as they relate to meetings of the whole association only, in the absence or inability of the president to act, and shall have an allowance for actual expenses, while performing said duties, upon the approval of the Advisory Board.

3. The secretary shall keep the minutes of the association; he shall collect all moneys, receipt for the same, and turn the same over to the treasurer promptly, and take his receipt therefor. He shall keep an accurate account of all receipts and expenditures of money, and make a report at each annual meeting of the association, and to the Executive Committee and Advisory Board whenever called upon so to do. He shall issue and mail all official calls and perform all other duties required of him by the association. He shall receive such salary, not to exceed $1,000 per year, as may be fixed by the Executive Committee, and shall have an allowance for expenses, to be paid upon the approval of the Advisory Board on presentation of properly executed vouchers. His salary shall be paid at the end of each quarter by draft upon the treasurer. He shall give bond in such sum as the Executive Committee may require, with security to be approved by the Advisory Board.

4. The assistant secretaries shall rank first and second, according to the choice of the association, and shall, in their order, perform the duties of the secretary in his absence or inability; and perform such other duties as the secretary may require of them, but shall not be members, nor act as secretary of the Advisory Board. They shall have such compensation as the Advisory Board may designate, and an allowance for actual expenses while performing the duties of their office, to be approved by the Advisory Board upon presentation of properly executed vouchers.

5. The treasurer shall receive from the secretary all money by him collected, acknowledge receipt thereof, and pay all properly executed orders and drafts, provided for in this constitution, and all other orders signed by the secretary and countersigned by the president, under the direction of the Advisory Board. He shall keep an accurate account of all moneys received and disbursed, and make an annual statement of the same to the association, and an itemized statement thereof to the Advisory Board at any time when he may be called upon so to do. He shall receive such salary, not to exceed $750 per annum, as may be fixed by the Executive Committee, and shall have an allowance for his actual expenses, after the approval of the Advisory Board upon presentation of properly executed vouchers. His salary shall be payable at the end of each quarter, by draft upon himself as treasurer. He shall give bond in such sum as may be required by the Executive Committee, with security to be approved by the Advisory Board.

6. ADVISORY BOARD.—The Advisory Board shall have full power to determine all questions, transact all business of the association at all times when the association or the Executive Committee are not in session; but shall carry out the policy adopted by the association, or the Executive Committee, unless in the opinion of the Advisory Board circumstances make a change of policy desirable. The Advisory Board shall direct the finances of the association, shall have full power to levy assessments whenever necessary, subject to the limitations contained in Article 3, and to appropriate money in the general fund to such use as, in its judgment, is essential to the welfare of the association. It shall create two funds in the hands of the treasurer, first, a fund for salaries and expenses of officers and committees; second, a general fund; and shall have power to transfer money from one fund to the other without interfering with existing obligations. It shall contract for the association, and shall at all times, except when the association or Executive Committee is in session, direct the other officers of the association to carry out the intention of this organization.

7. The Executive Committee shall have all the power of the association, except when said association is in session, not herein especially delegated to the officers and Advisory Board, and shall have an allowance for their actual expenses incurred in attending meetings of the Executive Committee, after presentation of properly executed vouchers, upon approval of the Advisory Board.

ARTICLE VIII.—REPRESENTATION.

Each member of this association shall be entitled to one vote for each 500 telephones or less, or for each 500 miles of toll line or less, in actual use, and one additional vote for a major fraction of 500 telephones or miles of toll line in actual use; and no more, on the election of officers or as to any question voted upon by said association.

ARTICLE IX.—QUORUM.

A majority of all members present shall constitute a quorum for the transaction of business of this association, twenty days' written notice of the time and place of holding the meeting having first been mailed by the secretary to each member of the association.

ARTICLE X.—EXECUTIVE COMMITTEE QUORUM.

Ten or more members of the Executive Committee shall constitute a quorum for the transaction of business, ten days' written notice of the time and place of the meeting having first been mailed by the secretary to the address of each member of the committee.

ARTICLE XI.—ADVISORY BOARD QUORUM.

A majority of the members of the Advisory Board shall constitute a quorum for the transaction of business.

ARTICLE XII.—SPECIAL MEETINGS.

The Advisory Board shall, whenever in its opinion the same is desirable, through its president and secretary, call special meetings of the association or the Executive Committee, as such times and places as it shall designate and a special meeting of the Executive Committee shall be called by the secretary upon the written request of three members of said committee, stating the object for which the committee is called, filed with the secretary at least twenty days prior to such meeting. The secretary shall thereupon notify each member in writing of the time and place of holding the meeting, and shall mail to each member a copy of the request for the same. A special meeting of the association may be called upon a written request therefor, stating the object for which the meeting is called, being filed with the secretary, when signed by not less than 100 members of the association. The secretary shall give ten days' written notice of the time and place of holding such meeting and shall mail to each member of the association a copy of the call for the same.

ARTICLE XIII.—SPECIAL SERVICES.

Any member of this association who shall perform special services under the direction of the association, Executive Committee or Advisory Board, shall be allowed such compensation and allowance for expenses as shall be approved by the Advisory Board

ARTICLE XIV.—ELECTIONS.

The election of officers shall be by ballot, whenever two or more names are presented for the same office, and shall be conducted by three judges and two clerks, to be selected by the presiding officer. The presiding judge shall announce the name of the voter before the ballot is deposited in the ballot box, and should any member challenge the vote, the judges shall then proceed to hear the objection and shall determine the rights of the voter. Members may vote by written proxy, duly authorizing another member or representative of a member to cast the ballot.

ARTICLE XV.—AMENDMENTS.

This constitution may be amended at any regular meeting by an affirmative vote of a majority of all the members of the association, and at any special meeting called for that purpose, the object having been stated in the call, upon the vote of two-thirds of the members present, the proposed amendment or amendments having been first signed by not less than twenty-five members, and filed with the secretary at least thirty days before said meeting, written notice of such proposed amendment or amendments having been mailed by the secretary to each member of the association at least twenty days prior to such meeting.

The following is a list of those in attendance, exclusive of manufacturers and supply men, whose names will be found in the notes on exhibits. All told about 300 persons participated in the convention.

Hugh Dougherty, Bluffton, Ind.: United Telephone Co., Bluffton: United Telephone Co., Portland; United Telephone Co., Huntington Ex., and Montpelier Telephone Co.

J. L. Stone, Rushville, Ind.: Rushville Co-Op. Tel. Co. and Shelbyville Tel. Co.

Joseph S. McKee, James M. Thomas and C. D. Duncan, Chillicothe, O.: The Home Telephone Co.

James M. Thomas, Marysville, O.: The Marysville Telephone Co.

C. D. Duncan, Chillicothe, O.; Chillicothe and Clarksburg Tel Co.; Londondery and Vigo Tel. Co.

Columbia Telephone Co., Waverly, O.

Londondery and McArthur Tel. Co., Allensville, O.

Dr. I. A. Lumpkin, Mattoon, Ill.: Mattoon Tel. Co.

Dan. A. Mossman, Huntington, W. Va.: Huntington Mutual Tel Co.

H. K. Cole, Owensboro, Ky.: Owensboro-Harrison Tel. Co.

Elmer E. Summey, Utica, N. Y.: Auburn Tel. Co.

D. C. Dow, Cobleskill, N. Y.: Cobleskill Tel. Co. and Cobleskill and Sharon Telephone Co.

Frank L. Beam and H. D. Critchfield, Mt. Vernon, O.: Mt. Vernon Telephone Co.

W. B. Seaton, Ashland, Ky.: Citizens' Tel. Co.

Tom A. Marshall, Keithsburg, Ia.: Tom A. Marshall Tel. Co.

W. B. Seaton, Ashland, Ky.: People's Tel. Co., Cattletsburg, Ky., and East Fork Tel. Co.

W. C. Sterling, Jr., Monroe, Mich.: Monroe New State Tel. Co.

William H. Blake, Cheboygan, Mich.: Cheboygan Tel. Co.

H. C. Young, Columbia, Pa.: Adrian Tel. Co.

H. C. Young, Columbia, Pa.: Columbia Telephone Co.

Dr. J. Williams, Jr., Adrian, Mich.: Adrian Telephone Co.

L. A. Carr, Durham, N. C.: Interstate Teleph. and Teleg. Co.

W. H. Gilbert, Saginaw and Bay City, Mich.: Valley Telephone Co.

CONVENTION NOTES.

EXPECTING SPIES. A curious feature of the convention was the unmistakable dislike and suspicion entertained in many quarters towards the American Bell Company, not merely as an opponent, but as a very bad and wicked entity. In one case, where the good faith of the delegate was suspected, a telegram was sent to his home making inquiries. The result vindicated him, but the incident left a rather disagreeable impression. It was gravely suggested by one or two ultra rabid independents that perhaps the arch enemy had spies concealed in the nooks and crannies of the hall. Another noteworthy feature was the zeal with which the delegates stuck to business. They seemed to read neither the local daily papers nor the various technical journals of largest circulation with which they were plied in the proportion of ten copies per delegate. They would talk all night, but reading at that juncture had no charms for them.

OLD BELL TELEPHONE MEN were to be found here and there in the throng, showing that after all the principle of heredity and continuity plays some part even in the most emphatic independent movements. It has been wondered where the opposition companies would find their talent. They have found it all right, and some very genuine advances and innovations may now be confidently looked for.

MR. J. D. LEATHERBEE, the fighting treasurer of the National Telephone Company, of Boston, was a personality of intense interest among the delegates when they learned that this quiet, earnest, reticent man was the center of the litigation with the Bell Company. It is only telling the bare truth that though Mr. Leatherbee went to the convention unknown to many Western delegates, his dignified conservatism and entire attitude won him great admiration among them. The efforts of the local papers to draw him out were not less numerous than amusing, but his confidences were courteously reserved for those entitled to them. It is gathered that the case in which Mr. Leatherbee's company is concerned will soon be in shape for argument, the evidence now approaching its close. It was generally recognized that Mr. Leatherbee has been fighting not for himself alone, but for the cause that the association as a body now represents.

THE ASSOCIATION was too young to have a button. Young Hercules choking a b—ll was suggested. For the present it wears as badge a tiny knot of baby pink ribbon, typical of the dawn of its career and the rosy nature of its hopes. Curiously enough, some of the delegates came wearing their N. E. L. A. buttons, showing how easy the step from electric light to telephony has been. One delegate had an N. E. L. A. badge that dated back to the Kansas City convention.

GETTING ACQUAINTED was in reality one of the features of the occasion. In the debates on the floor, the fact that the men did not know each other often came out in the amusingly periphrastic way in which they spoke of each other. "The gentleman over by the wall," or "My friend, I believe, from Indiana," and little things of that kind were very noticeable at the beginning. But after the boat ride on the St. Clair Flats that was all changed, and short, Christian names were in order.

JUDGE THOMAS made an admirable presiding officer. Indeed, there was a curious contrast between his nonchalant equanimity in the very hottest periods of cross-talk and the scathing indignation of his assault on the Bell policy. The task assigned him is no small one as president, and novel as the payment of a salary to such an official is, he is the man to earn the last cent of it. As usual, the presidency went to Ohio, for the Judge hails from Chillicothe.

THE DETROIT TELEPHONE COMPANY did the honors of their city in a very thorough and hospitable manner. All the delegates were welcomed to their splendid new exchange, where they could see a board no less than 173 feet long in one stretch, some 50 operators at work, and about 3,000 drops in actual service. Before the year is out the company expects to run up to 5,000 subscribers. Engineer-in-Chief Ahern and Mr. C. L. Zahm, the manager, did the honors very ably. Mr. Ahern has done some very fine work of an inventive and engineering character for the system, and is deservedly proud of his boards, operating room, subways, cables, etc. He is rapidly extending toll lines, and has already found it necessary to lay out a fine sub-exchange up Woodward avenue. For $40 or $50 a year the company is giving good service, as could be easily ascertained by casual inquiry around town. Messrs. Holmes, Hatch and McLeod, of the company, were also active everywhere in paying attention to visitors and friends and in participating in the work of the convention, in which they showed the utmost interest.

A DELIGHTFUL SAIL on the Detroit River and St. Clair "flats" was given by the Detroit Telephone Co. on Wednesday afternoon, when about 300 delegates and friends embarked at 1:30 on the steamer "Sappho." An excellent lunch was served with several "self-restoring drops," and the utmost good feeling prevailed. For several hours the boat cruised around, sounding once in a while for submerged Bell mines or torpedoes, as a measure of precaution. A band played appropriate airs of an "independent" character, and the pleasure of the trip was also enhanced by the relief afforded from the muggy heat of the city.

IT IS TOLD of one of the directors of the General Electric Co., that passing Schenectady the other day on the train, he inquired whose those fine factory buildings were on the side of the road! Some of the delegates to Detroit seemed quite surprised to find that a fine massive building near that of the Detroit independent company was operated by the Michigan Bell for telephone purposes, and one or two of them were observed trying to count the wires running into it, their comment being that it couldn't be an exchange with only that few!

A DELEGATE whose persuasive forensic eloquence was frequently heard in the convention was taking an active part in the final voting when the chilly statement was made that $10 dues must be paid before a vote could be cast. His work of canvassing votes ceased suddenly, he disappeared for several minutes, but could be seen behind some of the scenery on the stage groping assiduously about his person for a ten dollar bill. With a charming air of utter unconcern he slid back at last, paid up, and resumed his patriotic duties with as much fervor as though he had been, not one of the last, but the very first to sign the new constitution.

INTERVIEWS with prominent men in the convention, like Messrs. Thomas, Savidge, Blow, Taylor, McLeod, Keelyn, Dodge, and others, revealed the fact that in spite of differing points of view in policies, there was a common feeling of satisfaction in the fact that the independent interests had got together in such strong force. It was predicted that the movement would now be more rapid and pronounced than ever.

ATTENTION was called to the fact that the Eastern and Northeastern States showed up so sparsely at the convention, so far as operating independent companies were concerned. In reality, New England was a total blank, New York had a very slim deputation, and New Jersey "was not in it." The strength of the movement would seem to lie at present in the bunch of big States lying close together around Ohio, and in another big bunch including Indiana, Michigan, Wisconsin and Iowa. There is much interest to see how this ratio will continue to manifest itself. The State Association delegates present evidently felt that they were cuttig out some great work in their respective regions and that they had but barely begun.

EXHIBIT NOTES.

MR. W. S. ECKERT was present in the interests of the bi-metallic wire, and found ready listeners among the telephone men representing companies about to undertake new lines and seeking to give better competing service with circuits of a higher conductivity while securing the greater tensile strength.

BROWNLEE & CO., Detroit, Mich., the well-known manufacturers of poles and cross-arms for telegraph, telephone and other purposes, were well represented by their principals.

AMERICAN ELECTRICAL WORKS, of Providence, R. I., were represented by their Chicago agent, Mr. Edgar H. Hammond.

MR. E. RUEBEL, the president and treasurer of the St. Louis Electrical Supply Company, was present in the interests of that concern.

MR. P. P. NUNGESSER, the manufacturer of the admirable dry, chloride of silver and other Nungesser batteries, was present in behalf of the Nungesser Electric Battery Company. He is not only an inventor, but a practical chemist and electrician and has brought a long experience to bear on the subject of batteries. The products bearing his name are well known to telephone companies as well as to electrical people throughout the world.

STROMBERG-CARLSON TELEPHONE MFG. CO., of Chicago, were represented by Mr. A. B. Cotton, secretary; Mr. Delos Thompson and Mr. Hy. Shafer, and had a superb exhibit of well designed, beautifully built apparatus representative of their exchange, private line and other systems. Their transmitters and receivers are excellent pieces of mechanism and so constructed as to free from liability to danger of accident, the working parts being all carefully and thoroughly enclosed. The receiver is of the bi-polar magnet type, with solid brass head, and will hold up a dead weight of half a dozen pounds by sheer pull. These were all shown in working connection with desk sets, wall sets, long distance lines and as used in conjunction with the company's boards, all of which were equally interesting, providing for very rapid work by the operator, satisfaction to the subscriber, and facility for ready inspection and repair. Additional to all these were sets for police and fire alarm use, street railway complete sets to plug in on pole contacts along the road, and a very ingenious stenographer's set for direct dictation without leaving one's desk. There were also shown a variety of hand and power generators, extension bells, motors, triplet telephone sets to replace rejected apparatus of other makes right on the same backboard with the saving of all except the old receiver, transmitter and induction coil. It is hard to speak too highly of the cleverness and workmanlike style shown in the Stromberg-Carlson apparatus.

AMERICAN ELECTRIC TELEPHONE CO., of Chicago, were represented by Messrs. H. C. Dodge, general manager; P. C. Burns and a large staff of assistants. Their fine exhibit in Parlor G at the Cadillac Hotel consisted of their latest improved apparatus, such as their fine new "Express" switchboard, which was a great favorite with all who examined it, and which is being widely adopted. Mr. Dodge reported having closed under warm competition orders for a 700 express board, replacing another make, at Sandusky; one of 700 at York, Pa.; 800 at Shreveport, Pa.; 300, Monroe, Ill.; 400, Coshocton, O.; 300, Belleville, O., making all told a total of 5,000 drops ordered within 60 days. At St. Joseph and Benton Harbor, a 400 number exchange is now being built under their supervision. Among the other new apparatus shown may be mentioned the special telephone with adjustable transmitter arm, allowing fine adjustment both as to height and as to lateral position and maintaining the transmitter movement exactly plumb at all times. Their new solid back amplifying transmitter was also shown, which is now being used on several lines up to 500 miles in length, and which the American Company holds to be absolutely free from the slightest taint of possible infringement. The company, which has moved lately to Chicago, reports employing 137 hands, and putting out daily on the average 125 telephones and drops to the number of 150. Mr. Dodge spoke of the outlook for independent telephony as extremely bright.

WESTERN SIGNAL CO., at the Russell House, represented by the veteran electrician, Mr. B. F. Stewart, showed some very ingenious and taking apparatus, which embodies the idea of using the telephone in conjunction with certain automatic devices doing away with the great complication of the purely and more familiar automatic system. For instance, a man in case of a fire goes to the box and having begun he sends in the automatic signal, without further initiative on his part, by releasing the hook, which will tell the department headquarters the location of the fire. If the man has any senses left, or is an official, he can communicate by the telephone and state exactly the nature of the fire, its location in the block, and further particulars. The telephone is put in circuit by taking it off its hook. The signal goes in anyhow, and over a grounded circuit, while the talk goes over what becomes a metallic circuit. Another line that this apparatus is being introduced for is street railway work. The conductor carries the small telephone box on his car, it being 4 x 3½ x 5 inches, including a granular carbon transmitter, watch case receiver and the necessary connecting apparatus. In an instant by pushing the plug into the calling boxes put on the poles along the road, the conductor can reach his dispatcher or headquarters. He hangs his box up, plugs in and the central of the system is called up. The whole thing has been very neatly and deftly worked out.

WESTERN TELEPHONE CONSTRUCTION CO. were represented by Messrs. J. E. Keelyn, K. B. Miller, C. P. Platt, J. G. Nolen, W. D. Barnard and J. A. Russell, and had parlors for their wonderfully comprehensive exhibit put together in 48 hours under Mr. Russell's care. It was a central exchange in miniature and of the most complete character, besides being graced with a variety of detail apparatus and very handsome cabinet work. It consisted of a very fine exhibit of display board upon which the apparatus was mounted, comprising a telephone booth in the center with two wings on each side, in light wood. The various apparatus mounted showed a 100 drop switchboard complete throughout with all the latest details and improvements. A unique feature of the board was its compactness, its mechanical self-restoring drops and its new automatic circuit changers. The key table apparatus of a board has always been a cause of much trouble and annoyance. In this board, the operator by simply rocking a little lever to and fro, can get and put the calling and the called subscriber in quickest touch yet maintain control of the situation and thus expedite service all around. There were also shown some fifteen different styles of telephone instruments, including wall sets, desk sets, and different styles of mounts. A new long distance transmitter just put on the market was also put through its paces. It resembles the solid back of familiar design, but does not pack, can be refilled without dismounting the transmitter and is neat and handy. Various kinds of power generators, hand magnetos, etc., completed that part of the exhibit. Parts were also shown of regular 100 and 200 drop boards, mounted on a very handsome oak table. Every pains was taken to describe all the exhibit and illustrate its operation.

SMITH & PATTERSON, of 10 Warren street, New York, had on the hotel desk a very neat exhibit of their Ericsson telephone set as made in Stockholm, Sweden. Its novel style and beautiful workmanship, as well as its handiness of manipulation and good talking won it many encomiums.

THE KEYSTONE TELEPHONE CO., of Pittsburg, Pa., had a Cadillac Hotel parlor well filled with their substantial and businesslike apparatus. They were represented by Messrs.

Burt Hubbell, secretary and treasurer—the builder, by the way, of the first independent telephone exchange; and by Mr. J. G. Ihmsen, their courteous and efficient manager. They showed switchboard sections, their revolving granular type of transmitter, and their well-made bar magnet receivers and watch case receivers. They also exhibited their desk sets, intercommunicating system and other essential varieties of apparatus, and called special attention to a new and highly ingenious lightning arrester and protector, which allows any one line affected to be looped out at will without the slightest hindrance to operation of the others, and provides with marvelous cheapness and simplicity for the quick renewal of perfect connection. As an adjunct to telephone exchange operation it looks like a piece of apparatus sure to come into very general demand and use.

NATIONAL CARBON CO. had in one of the Cadillac parlors a very fine display of their many carbon specialties for telephone work, ranging from their latest types of batteries to their carbon for use in telephone apparatus. The exhibit was highly comprehensive and received much attention.

THE GARL ELECTRIC CO., of Akron, O., makers of telephone apparatus, were represented by Mr. M. Garl.

THE STANDARD UNDERGROUND CABLE CO. was well represented by Superintendent of Construction, F. S. Viele, who was about to point with pride to the large amount of excellent underground and cable work done for the independent Detroit Telephone Company.

ALLAN HUSSEY CO., of Chicago, makers of interior telephones, etc., were represented by Mr. A. R. Hussey.

MOON ELEC. MFG. CO., of Chicago, makers of telephone apparatus, were represented by Mr. A. H. Procunier.

NORTH ELECTRIC WORKS, of Cleveland, were represented by Mr. C. H. North.

RAWSON ELECTRIC CO., of Elyria, were represented by Mr. S. B. Rawson.

STANDARD TELEPHONE AND ELEC. MFG. CO., of Madison, Wis., were very efficiently represented by president H. A. Taylor, and secretary J. J. Nate, the latter of whom is a well known old-timer in electrical circles. Mr. Taylor is not only a telephone manufacturer, but is largely interested in exchanges, owns the Wisconsin "State Journal," and is actively in touch with many important enterprises and public policies in his own State.

VIADUCT MFG. CO., of Relay, Md., the old and famous makers of telephones and other electrical material were represented by Mr. J. Harry Lee.

COL. S. S. STOUT, a well known patent lawyer of Chicago, was one of the most interested and interesting men present. His sagacity and foresight were remarkably shown in a letter, familiar to many, addressed to the Telephone Protective Association in June, 1895, when he predicted with accuracy the results in the Berliner case and outlined the actual subsequent course of events.

PHOENIX INTERIOR TELEPHONE CO., of New York City, were represented by Mr. John H. Scofield, who was naturally a greatly interested participant in all that went forward.

WHITMAN & COUCH, the well known "Swedish instruments" telephone firm of Boston, were represented by Mr. Couch, who came in company with Mr. Leatherbee to voice the sentiments of independent telephony in New England.

W. R. COLE ELECTRICAL WORKS were represented by Mr. W. R. Cole himself.

ANDREWS-RYAN CO., of Boston, Mass., were represented by Mr. G. W. Andrews.

BISSELL, DODGE, ERNER CO., of Toledo, were represented by Mr. V. Bissell, from headquarters.

DETROIT SWITCHBOARD AND CONS. CO. were represented by Mr. F. M. Ashe.

TELEPHONE MFG. CO., of Sumter, S. C., were represented by Mr. F. C. Manning.

FARR TELEPHONE AND CONS. CO., of Chicago, already so well and favorably known in the telephone field, were represented by Mr. R. J. Cram from their home city.

WILLIAMS & ABBOTT ELEC. CO., of Cleveland, celebrated as makers of electric bells, etc., for telephone and other purposes, had a good exhibit of their product, doing justice to their various excellent specialties. Messrs. Williams and Latta not only upheld the reputation of the firm in this way, but scored heavily by their hearty and cordial hospitality, of which many delegates will have carried away a delightful impression. The concern is doing a large business and blazing the way for bigger.

CONNECTICUT TELEPHONE AND ELEC. CO., of Meriden, Conn., were well represented by their Mr. E. C. Wilcox.

THE ELECTRICAL PRESS was well represented, there being present Messrs. L. E. Powers, K. B. Miller, H. B. McNeal, Carl Kammeyer, T. C. Martin, W. J. McConnell, W. J. Johnston, C. T. Child, J. V. S. Church.

MR. J. H. CUMMINGS, of Cummings conduit fame, attended the meeting, being in Detroit, and met many friends. His company has not catered at all for telephone work, but this has not prevented the telephone men from knowing the claims for the Cummings system.

ORGANIZATION FORMED AT DETROIT OF INDEPENDENT TELEPHONE MANUFACTURERS.

The manufacturers of independent telephones met on June 23 at Detroit and held an enthusiastic and harmonious meeting, and organized an association to protect and promote the interests of the manufacturers and users of independent telephones. The following officers were elected unanimously:

President, H. A. Taylor, Standard Telephone and Electric Company, Madison, Wis.; Vice-President, S. B. Rawson, Rawson Electric Company, Elyria, Ohio; Secretary and Treasurer, J. Harry Lee, Viaduct Manufacturing Company, Baltimore,

An Executive Committee was formed, consisting of one member from each concern represented in the association.

Ample means were pledged to carry out the objects of the association and carry on any litigation brought against and repel all attacks upon the independent telephone business of the country.

The meeting was held behind closed doors, and no detailed report of the proceedings of the association was made public.

THE STOCK MARKET

A FIRM MARKET.

THE improved condition of trade is well reflected in the firm condition of the market for all classes of securities. An encouraging feature of the situation is the fact that exportation of gold, recently resumed, has had no effect on the prices of stocks, thus showing restored confidence on the part of investors.

General Electric is quoted at 33¼. Western Union rose to 83½ on good demand. American Bell remains firm at 231 bid.

Copper is quoted at 11⅛c. to 11¼c. for Lake ingot, and 10¾c. to 11c. for electrolytic; with 10½c. to 10¾c. for casting stock.

Steel rails are quoted at $19 to $20 at tide water.

LEGAL NOTES

WESTERN ELECTRIC CO. SUES THE HOME TELEPHONE CO. OF MOBILE, ALA.

The Western Electric Company has begun suit in the United States Circuit Court against the Home Telephone Company of Mobile, Ala., with connections throughout Alabama and Mississippi, for an alleged infringement of the patents of Charles E. Scribner's switch-board improvements. The Home Co. employs the system claimed by Paul Minnis, of New York. Messrs. Barton & Brown, of Chicago, will appear for plaintiffs, and Judge Charles B. Tilden and James E. Morris, the patent experts of Washington, are engaged for the defendants.

WESTINGHOUSE SUES BEACON LAMP CO.

Suit has been brought by the Westinghouse Company against the Beacon Lamp Company, for infringement of patent. The answer of the defendants to be filed in the U. S. Circuit Court at Trenton, N. J., will, we understand, raise the question of the existence of a combination to control the lamp business in restraint of trade.

MORE OF THE MANHATTAN-JANDUS — BUCKEYE IMBROGLIO.

A special dispatch from Cleveland, O., of June 16th says:— Novel proceedings in quo warranto were commenced in the Circuit Court to-day to declare forfeited the rights and franchises of the Buckeye Electric Co. to do business in Ohio. The proceedings grow out of an alleged abrogated contract between the Jandus Electric Company, of Cleveland, and the Manhattan General Construction Company, of New York. The Buckeye Company, it is claimed, was responsible for its broken contract by committing acts exceeding its corporate scope in Ohio.

The Buckeye Company is alleged to have purchased stock of the Jandus Company and carried it on the books as part of its assets. The Buckeye, by virtue of this ownership, is alleged to have assumed control of the Jandus Company's business and abrogated the contract with the Manhattan by the terms of which the latter was to sell goods made for and owned by the Jandus Company.

PERSONAL

MR. GEORGE A. McKINLOCK.

OUR readers will be glad to learn that Mr. George A. McKinlock, president of the Central Electric Company of Chicago, is now quite restored to health, and is again actively engaged in directing the large and increasing business of his company. Mr. McKinlock has not been in good health for over a year, but, refreshed by enforced vacation from the cares of daily business, he is now daily at his office and giving to his business that amount of concentrated energy which did so much to build up the success of the Central Electric Company, years ago. It is encouraging to note from a personal interview with Mr. McKinlock that business in the West is steadily improving, and the affairs of the Central Electric Company were never in better condition than at present. Orders are coming in from all over the Western territory, and the future looks extremely bright.

DR. HENRY MORTON, president of Stevens Institute, had the honorary degree of L.L.D. conferred upon him by Princeton University last week, in company with ex-President Grover Cleveland.

MR. J. C. O. MORSE, ex-superintendent of the State Reformatory at Hutchinson, Kan., has been appointed manager of the Water, Light and Power Company of that city. The plants include water works and electric light, gas and street railway enterprises.

MR. F. D. VARNAM has been elected assistant wire inspector of the St. Paul, Minn., wire department with a salary of $1,000 a year. The position has recently been created by city ordinance.

MR. PAUL M. LINCOLN.—The announcement is made from Niagara Falls that Mr. Paul M. Lincoln, the popular and efficient electrical superintendent of the Niagara Falls Power Company, is to wed Miss Elizabeth R. Hague, of Columbus, Ohio, on June 30.

MR. I. R. EDMANDS, of the General Electric Company, has gone West to take charge of the installation of the electrical machinery of the power development at Minneapolis and St. Paul, Minn.

CITY ELECTRICIAN GREENE, of Toledo, has resigned in order to take a more remunerative position with the Central Union Telegraph and Telephone Company.

LETTERS TO THE EDITOR

ELECTRICAL MANUFACTURERS AND DUTY ON MICA.

READING over the discussion about the tariff on mica in a late number of the "Congressional Record," amazement at the want of knowledge upon the subject as a whole on the part of our legislators is the feeling that dominates one who has happened to have a close connection with both the production and consumption of this remarkable article.

The general refrain is that mica is too cheap. If we could only increase the cost of mica three or even fivefold the country will be richer. If we could stop the importations profitable mines would be opened up in almost every State in the Union. Is this the truth? From my own experience it is not. The true cause of the low price of mica is owing to the fact that the supply greatly exceeds the demand. And even at the present low rate of prices the material is looked upon as a necessary evil, on account of its cost, by every consumer, and the tendency is to use pieces as small as possible. The smaller the piece used the greater the labor entailed; so in all cases an equilibrium has to be struck, which balances the price of the mica with the subsequent labor. If the price is increased smaller sizes will be used and vice versa. If the price is reduced large sizes can be used, and, what is of greater importance, owing to the over-supply, larger quantites also.

Every one knows that mica varies greatly in its properties, especially in hardness and transparency. North Carolina and Dakota mica and mica from other States stands at the head in combining these two properties—excessive hardness and perfect transparency—and this mica has nothing to fear from competition with that of other countries. It will always command a fair price, and, if the consumption is not interfered with, the mining industry in the States concerned will be in a healthy condition. The consumers of this quality of mica are the stove manufacturers, the makers of lamp chimneys, shades, etc., and, to a limited extent, the electrical manufacturers. Although the electrical manufacturers use this kind of mica where its qualities are required, the bulk of this kind happens to come both from Canada and India. Both countries possess mica of exceeding softness, the quality which is absolutely necessary for them, and Canada with its high-priced labor successfully competes with India; and so would this country if it only had the proper quality. This soft mica has not been discovered in this country and the electrical manufacturers must have it at any price, and no electrical engineer in his senses would think of using a hard mica where a soft one was essential. He would rather use a substitute, such as paper or fiber, which may be said to rank as the next best practical insulator. Paper at 3 cents, mica at 19 cents—a pretty bedfellow, to be sure. Any increase in the price of mica is certain to result in a decreased consumption, and it is to the interest of every one in the mica business, whether he be a miner or importer, that the price of mica be as low as possible. The increased sales at a low price will more than offset the small sales with a large profit.

Whatever tax is put upon the mica imported from other countries will not increase the price of mica mined in this country. There is already an overproduction. It would increase the price of the soft mica imported from Canada and India, and there would be a stronger tendency than there is now for the electrical manufacturers to use different substitutes. It is the electrical manufacturer who has scoured the world over to find a suitable cheap mica for his purpose, and the present duty of 20 per cent. is a severe tax upon his business, and the question of using mica is always before him. If from any cause the price is greatly increased a great blow will be struck at the mica business, and the miner, whether he be in Dakota or India will equally suffer. It will not only be the miner, however, but the electrical manufacturer also. There is no business in the country which has brighter prospects of sending its product abroad than that of the electrical manufacturer.

Only the other day one of them secured contracts in England and Australia entailing an outlay of over one million dollars. In fact, they are now looking forward to their export business as their chief outlet, and any tax upon them, when competing with England or Germany (and the one on mica is about the only one) might result in a loss of foreign business to the amount of millions of dollars. Mica, by the by, has played no unimportant part in securing these contracts. Owing to its large use American insulation stands very high abroad. This debate about mica in Congress shows a general pressure put upon the various representatives for a higher duty on mica. This pressure has come from those who own a bit of land with mica upon it. They are not in a position to know if a duty would help them or not. I most emphatically say that it would not. The remedy is a greater demand, not a higher price.

I may be like one crying aloud in the Wilderness, but for the benefit of the miners, the thousands of men and women who are employed in working the mica after it has been mined and for the mica business generally, I trust these few words will have a hearing.

MICA INSULATOR COMPANY,
Charles W. Jefferson, Manager.

New York City, June 18, 1897.

NEWS AND NOTES.

ELECTRICITY AT THE ROYAL SOCIETY.

A cablegram from London states that there were several notable electrical novelties at the Royal Society's soirée last week. Lord Kelvin showed conduction through air under the influence of uranium, the work being done in quasi-perpetual-motion manner by contact between uranium and zinc, aluminum, or air.

Mr. W. H. Preece, chief engineer and electrician of the British post-office, had an illustration in action of a system of signalling messages without wires by the use of a remarkably sensitive little instrument, the invention of Marconi[1].

Dr. Muirhead also exhibited a method of signalling by means of Hertz waves, as practised by Dr. Oliver Lodge in 1894, with a Branly tube of filings as a receiver and now adapted to the Kelvin recorder. An automatic telegraph transmitter, breaking the circuit of the coil and causing short sparks was placed in a distant room. The receiver was in a room near a responding recorder. The only source of communication between the two instruments was the waves of impulse sent through the intervening ether of space.

---

[1] See page 713.

Some new applications of Röntgen rays also excited much curiosity.

SOCIETY & CLUB NOTES

SIXTEENTH ANNUAL CONVENTION OF THE ASSOCIATION OF RAILWAY TELEGRAPH SUPERINTENDENTS.

The sixteenth annual convention of the Association of Railway Telegraph Superintendents was held at the Cataract House, Niagara Falls, on Wednesday and Thursday, June 16 and 17. The attendance was about fifty. In the absence of George M. Dugan, president of the association, Vice-President Lattig presided. The papers scheduled to be read were: "Relays and Their Resistance," by Thomas D. Lockwood, of Boston, Mass.; "The Apprenticeship System," by George C. Kinsman, of Decatur, Ill.; "The Delivery of Commercial Telegrams at Railroad Stations," by L. H. Korty, of Omaha, Neb.; "Railroad Telegrams," by C. Selden, of Baltimore, Md.; "The Telegraph," by A. R. Swift, of Chicago. The new officers of the association are as follows:

President—J. W. Lattig, superintendent of telegraph of the Lehigh Valley, at South Bethlehem, Pa.

Vice-President—W. W. Ryder, superintendent of telegraph of the Chicago, Burlington & Quincy, at Chicago.

Secretary and treasurer—P. W. Drew, superintendent of telegraph of the Wisconsin Central, at Milwaukee, Wis.

The association will hold its next convention in Hot Springs, Ark., June 15, 1898.

ELECTRIC TRANSPORTATION

EIGHTY MILES OF TROLLEY FROM BOSTON.

It illustrates the extent to which trolley extension has been carried in eastern Massachusetts, says the Meriden "Journal," to know that a party of gentlemen started out from Boston the other morning and rode eighty miles over a continuous series of trolley tracks, going as far as Lowell.

CONSOLIDATION OF BALTIMORE TROLLEY ROADS.

The Baltimore Consolidated Railway Company has been organized, the stockholders of the Baltimore Traction Company and the City and Suburban Company voting almost unanimously to consolidate the roads. The capital stock is $10,000,000, consisting of 400,000 shares at a par value of $25 a share. The new company will issue $12,000,000 4½ per cent. gold bonds, $10,500,000 of which will be used to retire the divisional mortgages as they mature, the remainder going into the treasury of the company. The combined trackage of the consolidated company is 185 miles.

One hundred and ninety-six thousand shares of the new stock goes to the Traction Company—of this 193,200 will be given in exchange for present traction stock at the rate of $21 per share, par value $25. The City and Suburban gets 163,600 shares of the new issue, of which 160,000 will be exchanged for the old stock of the City and Suburban, at the rate of $50 per share, which is par value.

The following are the officers of the Consolidated Company: President, Nelson Perin; vice-president and general manager, William A. House; treasurer, F. S. Hambleton. The directors are: Charles Adler, Edward L. Bartlett, Jesse Hills, W. T. Dixon, T. E. Hambleton, J. S. Hagerty, William P. Harbey, Nelson Perin, William A. House, Geo. C. Jenkins, George A. von Lingen.

The Mercantile Trust Company, of Baltimore, is trustee for the new bonds and also transfer agent. The consolidation takes place at once, but accounts will be adjusted up to July 1.

POWER TRANSMISSION

NEW USES OF NIAGARA POWER.

NIAGARA power has made another conquest. A contract has just been made between the Cataract Power and Conduit Company and President Hill of the Great Northern Railway Company and the Great Northern Steamship Company, whereby the Great Northern elevator now in course of construction in Buffalo is to be operated by Niagara power. The contract calls for 1,250 horse-power, and this the Cataract Power and Conduit Company will supply over their transmission line from Niagara Falls, they being the distributing agents for Niagara power in Buffalo. The new elevator will be one of the largest in the world.

Under Section 10 of the franchise granted to the Cataract Power and Conduit Company, said company was to be prepared to furnish 10,000 horse-power to consumers within the city of Buffalo on or before June 1897, but recently the aldermen of Buffalo granted the company six months' extension of time in which to do this.

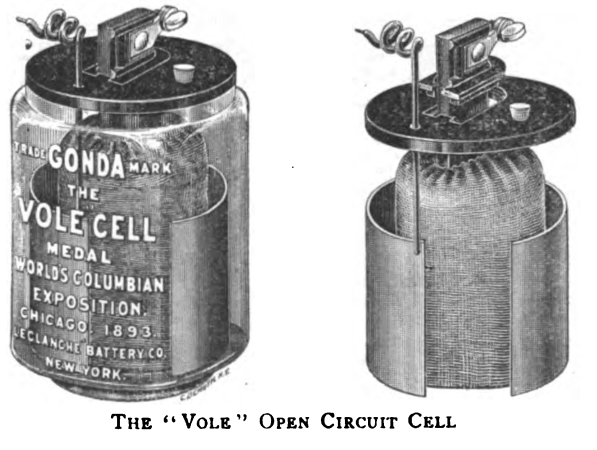
In Niagara Falls, Ont., the aldermen are discussing the prospects of developing power along the whirlpool rapids between the cantilever bridge and the whirlpool. Surveys have been made by an engineer named Mitchell, and he finds there is a fall of about 46 feet in the level of the river between the points mentioned. The commissioners of Queen Victoria Park have made surveys with similar results. The feeling is that many water powers with less fall have been made available. The land is controlled by the park commissioners, and the town of Niagara Falls, Ont., would probably have to contribute materially to the park revenues to gain the right to develop the power.

The Buffalo and Niagara Falls trolley line has recently made a change in its route to and from Buffalo whereby a saving of seven and one-half minutes is made each way, or fifteen minutes on the round trip. President Ely further says another change is in contemplation whereby another saving of fifteen minutes will be made, thus making the trip wonderfully short so far as time is concerned. "Through by lightning" seems to be the motto of the management of this road.

TRADE NOTES & NOVELTIES

THE "VOLE" OPEN CIRCUIT BATTERY.

THE "Vole" cell, made by the Leclanché Battery Co., of New York, has recently undergone a considerable improvement, so much so that it is claimed to be the best low-resistance open-circuit cell on the market, being specially adapted for electric gas lighting and kindred purposes, where large amperage is requisite.



THE "VOLE" OPEN CIRCUIT CELL

The negative electrode of the "Vole" cell, as shown in the accompanying engravings, consists of a carbon, having projecting vertical wings, over which is stretched a bag so as to form pockets between the wings for the reception of the depolarizing material. The electrode is suspended (in a jar) from the cover by a patented forked center-piece, which slips on the carbon under its head and rests in an opening in the cover through which the carbon passes. The zinc is a cylindrical sheet, the lower end of which rests in the channel around the well at the bottom of the jar. To the zinc is soldered a gutta-percha covered zinc wire, intended to pass up through the smaller hole in the shoulder of the jar, for connecting to the carbon of the next cell or to the line wire.

The neat little catalogue of the Leclanché Battery Co. gives full descriptions of the "Vole," "Gonda," and "Axo" batteries manufactured by the company, together with a digest of useful electrical and other data.

MAYRHOFER'S STAGE LIGHTING APPARATUS.

Mr. J. Carl Mayrhofer, of 28-32 Centre street, New York, will shortly issue a new and complete edition of his catalogue for the season of '97 and '98. The forthcoming catalogue will be complete in every detail, embracing many new features, and describing numerous electrical, optical and mechanical effects, some of them never before introduced in any stage productions.

A considerable space in this new issue will be devoted to the detailed description of new Mayrhofer arc light apparatus and effects.

The new '97 constructions embody every conceivable requirement and improvement that long experience and practical use have shown to be of value, and represent the most advanced type of modern stage lighting apparatus at a moderate cost.

The catalogue will be sent on application.

NEW YORK NOTES.

BUFFALO, N. Y.—The Acme Malleable Iron Works are erecting an absolutely fire-proof building for the storage of their patterns. This building is 30 feet wide and 60 feet long. The building will be constructed of non-combustible material, and the frame work will be of steel, the covering of corrugated iron, and the racks supporting the patterns will also be made of metal. The Berlin Iron Bridge Company are furnishing and erecting the steel frame work and covering.

THE ELECTROZONE COMPANY has removed its offices from the Morris Building, Broad street, to 415 Lexington avenue, corner Forty-third street, where it will attend to its growing business with better facilities. Electrozone has become very popular as a purifier and disinfectant.

FRED. M. LOCKE, of Victor, N. Y., has recently issued a very neat and interesting pamphlet on the subject of his high insulation line insulators, steel pins, brackets, break arms, etc. The material is well illustrated and thoroughly described. Mr. Locke's work has lately been associated with some of the longest power transmissions in the country.

C. A. ECK, Newark, N. J., reports receiving orders which will keep his factory busy throughout the summer season. Mr. Eck manufactures fan motors, dynamos, etc.

WESTERN NOTES

THE ELECTRIC APPLIANCE COMPANY have been so very successful in the introduction of the American electric soldering iron, that they are preparing a circular of a few of the many testimonial letters received from customers in regard to the operations of these irons. The Electric Appliance Company look for a very large sale of these goods, as a satisfactory electric soldering iron has long been wanted.

ST. LOUIS LIGHTING.—The Western Electric Company, through Mr. F. W. Crandall, has now sold out its lighting interests in St. Louis to the local Edison Illuminating Company, which thus consolidates all the central stations in the city.

WATER WHEELS.

IN the article on "The Principles and Construction of Water Wheels," appearing in our issue of May 19, there appeared an illustration, on page 529, showing the comparative size of overshot water wheel and turbine. The credit for this graphic illustration belongs to the James Leffel & Co., in whose trade publications it appeared originally.

REPORTS OF COMPANIES

IMPORTANT SIEMENS-HALSKE DEAL.

The Siemens-Halske Electric Company is, it is announced, to be at once consolidated with the Pennsylvania Iron Works of Philadelphia, with a combined capital of $3,250,000.

THE W. J. JOHNSTON CO., LTD., publishers of "The Electrical World," have applied to the New York Supreme Court for a voluntary dissolution of the company and September 23 is set as the date for a hearing on the order to show cause. The liabilities are $3,420, and assets $8,930.

ELECTRIC TRANSPORTATION

WILLARD STORAGE BATTERY LAUNCHES.

AMONG the recent work done by the Willard Electric & Battery Company, of Cleveland, is the installation of a complete storage battery outfit in two launches used by the W. F. & John Barnes Company, of Rockford, Ill. Our illustration, Fig. 1, shows the launches which present a very trim appearance.

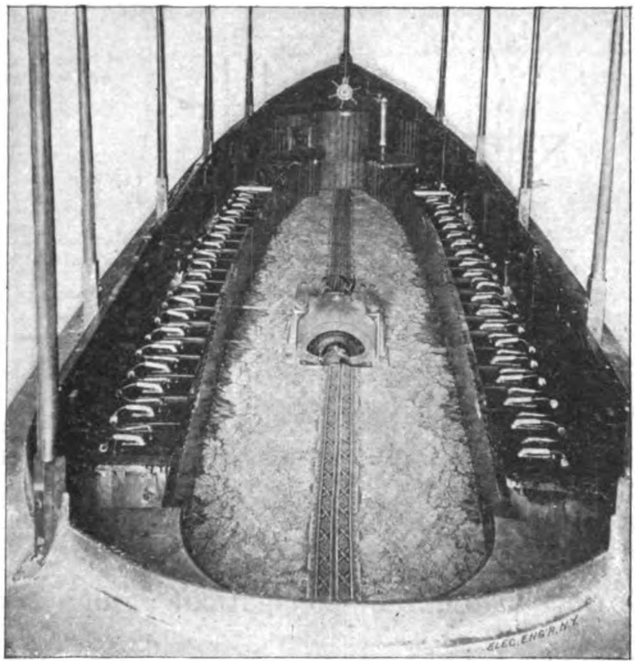

FIG. 2.—WILLARD STORAGE BATTERY LAUNCH.

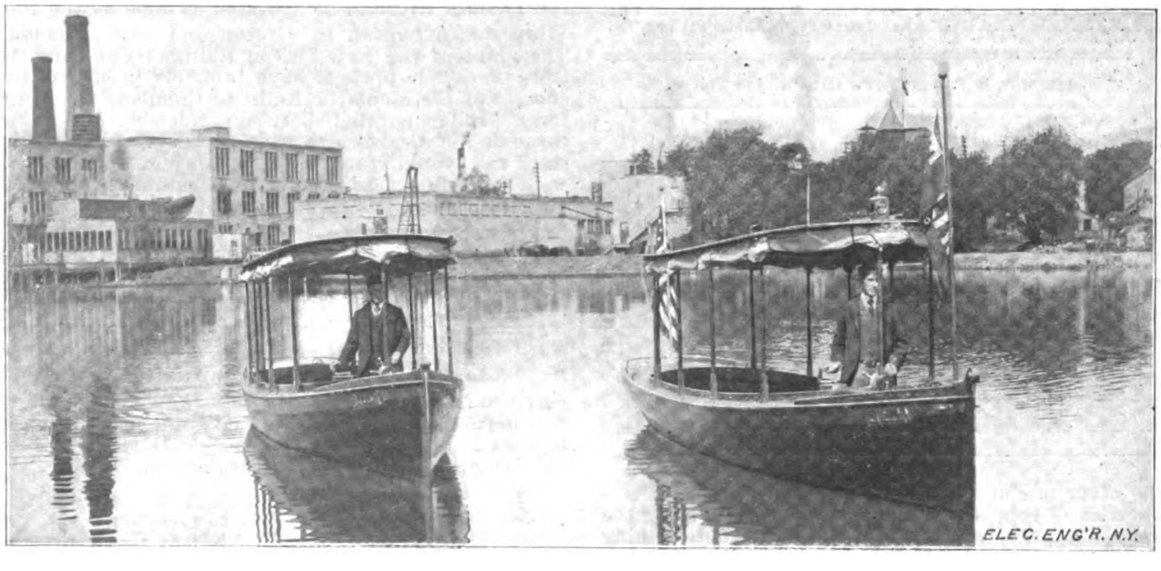

FIG. 1.—WILLARD STORAGE BATTERY LAUNCHES.

The launches are 30 feet long, 6 feet beam, and draw 22 inches of water, with 40 Willard type "G9" Cells. These launches are capable of attaining a speed of 14 miles an hour. The motor, as will be seen from the illustration, Fig. 2, is connected directly to the propeller shaft, is easily accessible, and takes up very little space. The launches have been in operation the past three months and are giving excellent satisfaction. The Willard Company have fitted out quite a large number of electric launches, and those illustrated are representatives of the most popular type and size.

The Willard storage cells possess unusual qualities for this class of work, owing to their peculiar construction. The elements are so encased that the rolling motion of the boat does not interfere in any way with their operation.

TROLLEY LINE CONSTRUCTION DATA.

A PUBLICATION containing an unusual amount of valuable information is the catalogue on "Trolley Poles," just issued by the National Tube Works Company. Besides giving full information as to sizes of their standard and extra strong poles the little booklet gives a brief but excellent description of the best methods of erecting steel trolley poles.

Beginning with the foundations, it describes the methods illustrated in The Electrical Engineer Data Sheets, Nos. 5751-4, 5 and 6, and gives tables of various lengths of trolley poles.

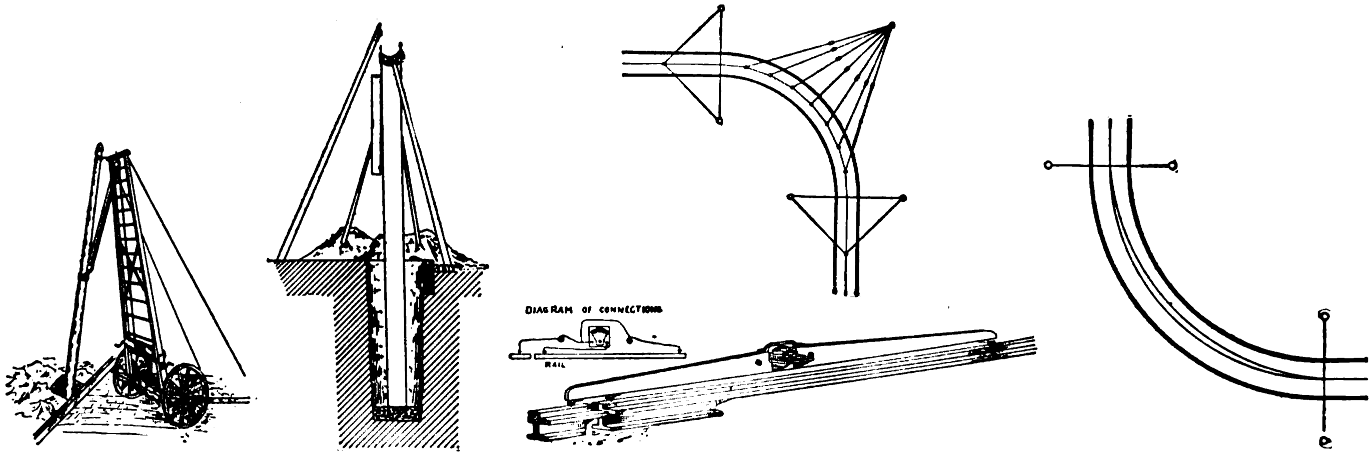
The method of erection is described as follows:

The method of raising the poles and lowering them into the holes is generally done by a portable derrick mounted on a heavy dray, together with a crab winch, see Fig. 1. This is driven as close to the pole hole as possible—the pole previously being rolled parallel to the road, as close to the hole as convenient, or it can be raised directly from the dray. A chain is rigged around the pole a little above its center of gravity, and the pole raised up into a vertical position, and the derrick moved over until the pole is directly over the hole. The bottom end of the pole should be plugged up flush with wooden plug at least 6 inches long, and it should have had at least two coats of good anti-rust paint. The pole is guided down the hole against a skid plank until it rests on the 8 inches of cement and guyed into position, see Fig. 2. The rake of the pole should be from 8 inches to 12 inches, depending on the flexure of the pole and the character of the foundations. A level is very useful for varying and determining rakes, and by sliding a 1¼-inch projection on one edge of the level any rake can be determined from 7½ inches to 15 inches for a 24-foot pole, and the pole can be set by means of this level.

It is well if a large stone can be placed at the heel of the pole, then more cement is put in and tamped around the pole, tamping thoroughly every few shovels full, until it is within 4 inches of the top. The top should be finished off, as shown in sketches for pole foundations, so as to drain the water away from the pole, as the point at the surface of the earth is the point where the pole deteriorates most rapidly, and is subject to the greatest strain. No caps or rings should be used, as any rusting here affects the strength of the pole, and if a steel pole is thoroughly protected at this point it is a permanent structure. Poles should be allowed to stand from eight to ten days for the concrete to set before the line is erected.

Curves.—Where an electric railway changes its direction the trolley line must conform in some degree to the path in which the car diverges, in order that the trolley does not leave the trolley wire. In all forms of overhead curve construction the trolley wire is pulled into a polygon approximating the curvature of the track.

All tensions should be taken off the trolley wire at the end of both tangents to the curve; this can be done by running strain wires to take up this tension, as shown in Fig. 3. The location of the trolley should not be over the center of the track at the middle of the curve, as the car body forms a side of a polygon as it sways around the curve. In the center of the car is located the base of the trolley pole, and consequently the trolley wire should be guyed in at shorter curvature than the radius of the track, see Fig. 4. For a curve with a radius of 50 feet, the trolley wire should be 8 inches inside of the center of track at the center of a curve for two tangents at 90 degrees. A table gives what this departure should be to keep the trolley on curves from 35 feet to 350 feet radius, also the distance in feet that pull-offs should be spaced, so that the deflection of the trolley wire at any one point will not be sufficient to throw the trolley in passing around the curves. Many different ways of guying have been devised, and several of the most commonly used methods are shown.



FIGS. 1, 2, 3, 4 AND 5.

The strains brought on poles acting as master poles for curves warrant ordering larger and longer poles, so that they can be set from 7 feet to 7½ feet deep, and the hole should be dug at least 26 inches in diameter that is to be filled with concrete. The pole may be given more rake than allowed in straight line work.

THEORETICAL WATTS PER TON OF 2,000 LBS. AND PER MILE PER HOUR, WITH VARIOUS GRADES AND TRACTION COEFFICIENTS.

Among the other useful information are several tables giving the properties of copper wire, a chart for determining the size of feeders, together with a rapid method of determining the resistance of the rail joint in terms of the rail resistance. The latter is as follows: By using a milli-voltmeter having the zero in the middle of the scale, this relation of joint to rail resistance can best be found by the arrangement shown in Fig. 5.

Mount the milli-voltmeter on a straight edge about 6 feet long, three drop points being secured to the bottom of the straight edge and flexibly mounted to a spring, as it is necessary for all these points to make contact on the rail where the straight edge is pressed down. This device is carried along the track and the connections are best made on the tram of the rail, the joint being included between those two drop points, one foot apart, leaving a length of rail 5 feet between the other two points. Resistance spools of about 10 ohms each are placed in circuit with the milli-voltmeter. The deflection of the voltmeter one way will be due to the current flowing in the rail; the other way the drop will be due to bond resistance, and the two deflections bear the ratio of the bond to rail resistance, or certain deflections can be fixed above which the bond should be replaced, and these imperfect joints can be marked for repairs. About two miles can be done in one day of double track by this method.

We also notice the accompanying table of the power in watts required to move a given load at various speeds, grades and traction coefficients.

ANOTHER PROJECTED CONNECTICUT THIRD-RAIL LINE.

On July 15 the present repair shops of the Norwich and Worcester Railroad Company, at Norwich, Conn., will be discontinued, and the work divided between the shops at East Hartford, Conn., and at Norwood, Mass., of the New England Railroad Company, which leases the Norwich and Worcester. The vacated shops at Norwich will be fitted up as a power station to operate a projected third-rail on the east side of the Thames River to be operated as soon as the Norwich and Worcester extension to Groton and New London is made. The plans of the New Haven Railroad Company, which controls the whole project, have probably been expedited by the success of the Montville Railroad Company in getting its plan for a trolley parallel between Norwich and New London through the Legislature in a disguised form. The proposed third rail would reach for a distance of about fourteen miles, with opportunity to extend to Stonington, and make Watch Hill and other summer resorts much more accessible than now.

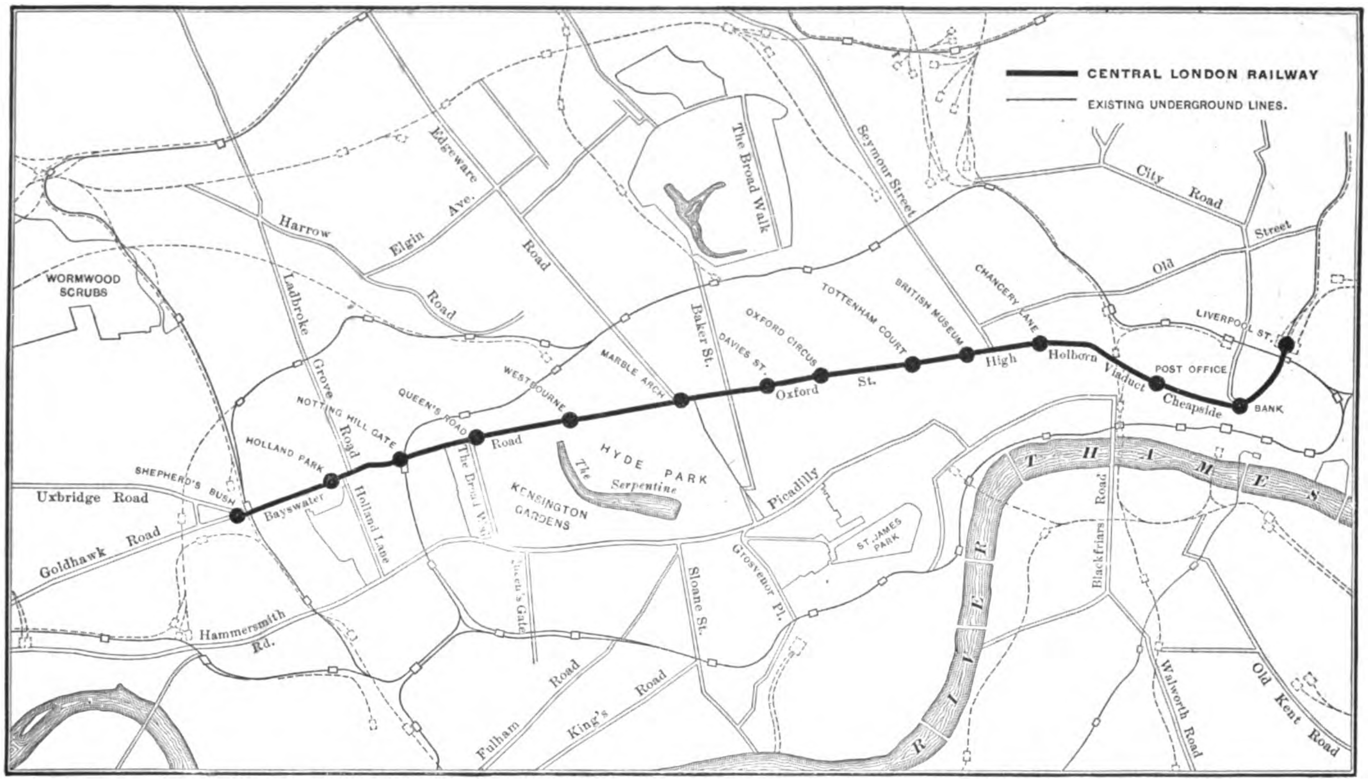
ELECTRIC RAILWAYS FOR GHENT, BELGIUM.

The last Consular Report contains a letter under date of April 16, from Consul Morris, at Ghent, Belgium, calling attention to the proposed electric railway in that city. It is proposed to use accumulators within the city and the trolley system beyond the city limits. The franchise will be sold to the highest bidder. Plans and specifications have been sent to the Department of State, Washington, D. C.

PRESIDENT H. H. VREELAND, of the Metropolitan Traction Company, New York, expresses the belief that the substitution of electric for horse traction on Madison avenue, just sanctioned, will result in a 50 per cent. increase of traffic, using larger cars, but not more of them, at a higher rate of speed.

ELECTRICITY ON THE LONDON CENTRAL UNDERGROUND.

THE most recent addition to the system of underground railways with which London is provided and the most important of all the present undertakings of a similar character in the world—the Central London Railway (Underground) has an especial interest for Americans. This is due to the fact that the entire system of electrical equipment will be American. With the exception of the elevators, of the famous Sprague make, the entire electrical contract has been assumed by the British Thomson-Houston Company, Limited, representing in Great Britain the General Electric Company, of Schenectady, while the elevator contract has been secured by Mr. Frank J. Sprague, of New York. The road, laid in two deep subway tunnels, driven by the Greathead Shield, stretches from Liverpool street beneath the station of the Great Eastern Railway Company, near Broad street, the city terminus of the North London Railway and the Bishopgate Street Station of the Metropolitan Underground Railway, through the very center of the great commercial district of the city and runs due west under Holborn, High Holborn, Oxford street, and past Hyde Park, as far as the Generating Station located at the terminus at Shepard's Bush. It follows the line of greatest traffic in London. The road will receive passengers from the great underground central depot, now in course of construction by the Central Railway Company, between the Bank of England and Royal Exchange, passengers brought in by the main lines of the London and Northwestern, Midland and London and Southwestern railroads. It is especially at this point in the city that crossing is a perilous task, and the railroad company is now engaged in constructing a series of subways immediately below the surface for the convenience of pedestrians and as approaches to its own station below. From this central depot will radiate not less than five underground tunnels, some 85 feet below the surface, each feeding a separate and equally populous district of the great agglomeration known as London.



MAP OF THE LONDON CENTRAL UNDERGROUND ELECTRIC RAILROAD.

The construction of the road itself has been carried out by the Electric Traction Company, which has also financed it. It is this company that has made the contracts with the British Thomson-Houston Company, which will turn over the road fully equipped and in working order to the Central London Underground Railway Company ready for operation.

It was not until three years after the necessary parliamentary act was passed in 1893 that the actual work of building this road could be undertaken. Vertical shafts were driven at six different points to a depth of 60 feet and 70 feet, and the tunneling was begun in four tunnels at once, two running in each direction from the shaft. At each of the stations were driven two shafts 23 feet in diameter and 87 feet deep, and one 18 feet in diameter and 76 feet deep—the two former containing two ingress and two exit elevators and the smaller two spiral stairways, one for ascending the other for descending passengers. The shafts are built up of cast iron plates 1⅛ inches thick and 4½ inches in the flanges. All crevices in the back of the plates are filled with hydraulic lime grout injected under pressure. The glazed white brick passages leading from the bottom of the shafts to the stations are 8 feet 3 inches wide on the entrance side. On the exit side, where crowds might collect in front of the elevators, they are 13 feet wide.

At the stations the widened tunnel is 21 feet in diameter and 375 feet long. The main tunnels are each 11 feet 6 inches in diameter, and are practically steel tubes driven forward through the clay. The plates used to line these tunnels are ⅞ inch thick, with flanges 4 inches deep. The shield for driving the small tunnels was 12 feet 8 inches in diameter and was pushed forward by six hydraulic rams giving a pressure of 230 tons. For driving the station tunnels the shield was 23 feet 8 inches in diameter, and was pushed forward by 22 rams giving a pressure of 840 tons.

Each tunnel will contain one track, one tunnel carrying the eastbound trains, the other the westbound trains.

In laying the roadbed, the best modern steam railway practice has been followed. The steel rails weigh 100 pounds to the yard, and are laid upon heavy-crossties. The system of contact will be the third rail, with the contact rail placed between the service rails of the track and insulated by insulators. The conductors will be supplied at intervals from a copper feeder cable. This feeding will be controlled from the signal boxes, and the operator will be able to cut out any section of the line when necessary. This method of contact is similar to that employed so successfully by the General Electric Company in the installations on the East Weymouth, Nantasket Beach and Berlin-Hartford branches of the New York, New Haven and Hartford Railroad. The method of traction, however, will differ radically from that used on the branches above mentioned. Instead of passenger-carrying motor cars, with the motors mounted on the forward axle, locomotives similar in appearance to those used on the Belt Line tunnel service of the Baltimore & Ohio will be used to haul the trains. The reason for this lies in the fact that the tunnel is only 11½ feet in diameter, and that the bottom of the tunnel must accommodate the roadbed. This materially reduces the clearance. The motors require to be suspended between 30-inch wheels, at least, to give the necessary clearance between them and the ground, and this fact has brought about the locomotive in place of the passenger motor car.

The total length of the road is 6½ miles, from the station at Shepard's Bush to the Mansion House, or 13 miles of single track. There will be fourteen stations, including the termini. In designing the line a decided departure has been made in the arrangements of the station approaches. As the railway company is not embarrassed by any considerations of grade, as in the case of surface railroads, the plan was adopted of making the road act as an auxiliary to the operation of the trains as well as merely to carry them. On each side of each station is a 3 per cent. gradient, rising on the approaching side and falling again to the level of the road on the departing side. This unique method gives a retarding effect to all trains approaching the stations, equivalent to the application of considerable braking power, while materially aiding in the acceleration of all trains as they leave the platforms. Furthermore, the saving in power necessary to secure requisite rapid acceleration is by the adoption of this plan calculated to amount to about 33 per cent. The schedule speed of the trains will be 14½ miles an hour, with stops at each station of 20 seconds. The trains will be run at first under a headway of two and a half minutes, which will be reduced as soon as the traffic demands to a headway of two minutes.

The generating station will be located in the open air at the extreme western end of the line near Shepherd's Bush Station. In building this the most modern American methods will be followed. The steam will be supplied from Babcock & Wilcox boilers, and the engines, of which there will be six, will be horizontal Allis machines, each of 1,300 h. p.

The electrical system adopted is the three-phase alternating high voltage primary with reducing transformers and rotary converters, similar in general principle to that installed successfully by the General Electric Company for the roads between Lowell, Mass., and Nashua, N. H., and at Portland, Oregon, between Niagara Falls and Buffalo, and on the line between Dublin and Dalkey, in Ireland. The dynamos, of which there will be six, will each be directly driven by its own engine. These dynamos are of the newly developed rotating field and stationary armature type, already illustrated in The Electrical Engineer. Each will have a capacity of 850 kilowatts. The speed of revolution will be 94, the frequency 25 cycles, and the initial voltage 5,000 volts. The total capacity of the power station will be 5,100 k. w., or 6,800 h. p.

From the switchboard the current is carried to the converter sub-stations, of which there are four. Two of these will contain seven step-down static transformers, six for service and one in reserve, each of 300 k. w. capacity, and two rotary converters, each of 900 kilowatts capacity. The other two stations will contain four 300 kilowatt static transformers and one 900 k. w. rotary converter. In the transformers the voltage of the current will be reduced from 5,000 volts to 330 volts alternating, at which pressure it will enter the alternating side of the rotary converters, issuing from the commutator side direct railway current at 500 volts. The spare transformers mentioned above will be put into service when the headway of the trains is reduced. The static transformers are of the air blast type, the windings being cooled by air forced through them by a blower. The rotary converters will be similar in construction to those used at Niagara, Buffalo and Nashua.

The use of the sub-station method of electrical distribution insures a uniform pressure throughout the entire length of the line. Fluctuation, therefore, which would materially interfere with the lighting of the station and trains, is reduced to a minimum. The limit of variation fixed by the Board of Trade, to the rules of which department all electrical installations in Great Britain must accord, is ten volts. With the method adopted in this installation, the variation in pressure will not exceed three volts.

The locomotives will number 35. Each will consist of a sheet iron cab containing the controller, indicating instruments, air brake, pump and controller, sand boxes, etc., mounted upon a locomotive truck. The motors have been especially designed for this work. They are of the gearless type and according to the new system of motor nomenclature adopted by the General Electric Company, are known as the G. E. 56. Four of these motors will be mounted on each locomotive, one to each axle, the total drawbar pull being 14,000 pounds. The controllers will be of the series parallel type arranged for four motors. Each controller will embody the magnetic blow-out principle.

The weight of each locomotive complete will be 35 tons of 2,240 pounds. The trains will be made up of seven cars, weighing, when loaded, 105 tons additional, giving a total train weight of 140 long tons. The seating capacity is calculated at 336 persons.

Access to and exit from the stations will be effected by means of powerful high speed elevators. These will also be of American manufacture, and will be built by the Sprague Electric Elevator Company, of New York. The elevators will be forty-nine in number, each will have a capacity of 15,000 pounds, or about 100 passengers per trip. The speed of elevation will be about 150 feet per minute. These elevators will be of the double drum type similar to those built for the War Department, at Washington, but of much higher carrying capacity.

It is estimated that the number of passengers which this road will carry per annum is 48,000,000, which, at an average fare of 4 cents, will give an ample return to insure dividends upon the capital stock.

A SPECULATION REGARDING THE CAUSE OF ROENTGEN RAYS.

BY PROF. ELIHU THOMSON.

SINCE so eminent a physicist as Prof. J. J. Thomson has in a recent paper put forward the hypothesis of the breaking down of what we have been accustomed to call the "elements," and has shown a reasonable basis for such a hypothesis, the writer deems it not improper to state that a similar view had quite independently risen in his own mind, the origin and progress of which may, it is thought, be interesting to others working and thinking in the same field. No apologies are offered for indulgence in the speculations herein presented. They are not presented as scientific theories, demonstrable by appeal to facts, but may possibly aid in investigation, and they are, therefore, given for what they are worth.

For some years past the writer has felt that some light might be shed upon the nature and relations of the so-called elements could we attain exceedingly high temperatures by any means. The elements may have been evolved in the order of their complexity in a manner similar in some respects to the species of plants and animals.

About four or five years ago an experiment was planned as one possibly capable of permitting temperatures far exceeding that of an electric arc, our present limit, to be obtained. A temperature of less than 4,500 degs. C. above absolute zero is not high when it is remembered that there can be no upper limit assigned to possible temperatures. Our chemistry is now all confined, so to speak, within lower limits than 4,000 degs. C. to 5,000 degs. C., and even within these limits most known compounds are decomposed or dissociated. Can we not raise our plane of temperature and give birth to a new chemistry in which the present elements, though apparently stable hitherto, shall become dissociated into simpler forms; for, that they are complex is to be inferred from the complex spectra which all, not excepting hydrogen itself, possess.

It was seen that the temperatures attainable by electric means were limited by the volatility and consequent expansion into vapor of the substances subjected to electric current, but that if the expansion could be prevented there might result the possibility of securing indefinitely high temperatures. To do this it was planned that a very strong and thick but short cylinder, of tempered steel, should have a small central opening through it so as to make it into a thick tube. This was to be lined with an insulating lining of some simple compound, as magnesia, for example, in a perfectly pure state. A core or wire of, say, metallic magnesium, was to pass through this, after which carefully insulated heads or caps were to be very solidly clamped to cover the ends of the cylinder and form the terminals for the passage of an electric discharge. This would pass from head to head through the central core (wire of magnesium).

This discharge was to be that of an enormous condenser charged by alternating currents furnished by a step-up transformer and the amount of energy to be delivered in a fraction of a second was to be made very large. The operation would be nearly instantaneous and should result in enormously high temperature of the material within the steel shell. There could be no expansion to lower the temperature. A spectroscopic examination was to be made of all the materials present before the experiment and a similar examination after the experiment, should declare the presence of any element not there before.

Reasoning on the idea that many complex compounds arise from sudden heating and cooling of comparatively simple compounds, it was thought possible that if dissociation of elemental forms took place at the enormously high temperatures the cooling would probably give rise to small amounts of the denser elements, discoverable, perhaps, by the spectroscope. These denser elements were to be the "elemental tars" or "polymers" of simple ones subjected to experiment. The experiment was to be varied in many ways.

This general proposition was described to several associates at the time it was thought out. Among these are several well known workers, such as Mr. C. P. Steinmetz, Mr. E. W. Rice, Jr., Mr. Robert Shand and others. The plan was recognized as a basis for a possibly fruitful research. There was no opportunity to prepare for the work and the idea was allowed to rest, in the hope that the future would yield the coveted freedom to undertake it.

After two or three years the discovery by Röntgen of the peculiar radiation from the Crookes tube, led to the writer's giving considerable time to investigation of the actions occurring and probably as a consequence of the prior thought in relation to elemental dissociation, the idea came that in the Crookes bombardment stream the conditions, upon collision with the platinum anode, must represent those of an exceedingly high temperature of the gas. With certain exciting apparatus of great power it was found that the bombardment was so energetic as to heat in a few seconds an anode plate one-sixteenth inch thick and an inch square to intense glowing heat. Considering the small mass of the molecules of gas projected from the cathode, the velocity of their movement was seen to be extremely great if they were to convey the energy delivered in so short a time to the platinum anode. The layer of gas immediately in front of the platinum must, it appeared, reach an extremely high temperature and represent in a measure the conditions sought for in the proposed experiment with the steel tube above described.

The question arose, Could it be that the increase of vacuum was after all due to the formation out of the gas, of small amounts of denser materials, or even that the elementary gases were decomposed at the high temperatures only to re-form on cooling, but with a small "tarry" residue, so to speak, polymers, perhaps, or denser, non-volatile elements? If this were so, then the gas should eventually all disappear in the same way. It does disappear, but how? We have guessed, but may be mistaken. We need to know more of it.

Considering these matters it occurred to the writer that a cause for the production of Röntgen rays might be found if the elements were dissociated into simple or more primordial matter. Taking the view, which has much to support it, that in the spectrum of ordinary heat and light we find all those rates of electric oscillation which characterize vibrating molecules or the atoms of elements composing them; that they set waves up in the ether because the ether is essentially electromagnetic; that the great rigidity of the ether so opposed to its apparent extreme mechanical mobility is after all only a chemical or electromagnetic rigidity, bearing no proportion to its mechanical properties, any more than the ordinary fluidity of a chemical compound bears to the chemical stability of the compound, we arrive at an interesting supposition respecting the Röntgen ray emanation. If the residual elementary gases are broken up into simpler and finer matter within the area of the bombarded spot, the normal electromagnetic rates of vibration of that finer matter should be far higher in pitch or of shorter wave lengths than in the case of the ordinary spectrum.

According to this view there would be no oscillation so slow as ordinary light originating in the finer matter dissociated from the elements at the exceedingly high temperatures represented by the colliding molecules or atoms immediately at the front of the platinum anode. All the wave lengths emitted as normal to the new forms of matter, only existent at the highest temperatures, would be of the Röntgen ray order, and a spectrum of such rays might characterize the matter present, as the ordinary spectrum does the low temperature combinations. But absence of diffraction and refraction effects thus far are formidable obstacles to such analysis of these higher pitch rays.

The absence of the lower or Hertzian waves from sunlight probably depends on there existing no molecules or atomic aggregations in ordinary matter which can possibly vibrate electrically at such low rates. So in the hot primordial matter no ordinary light waves need be generated, but only the higher order known at Röntgen rays. The latter are the normal vibrations occurring in such matter. The spectroscope cannot help us in the analysis of these higher waves and the forms of matter giving rise to them.

Further, if in the universe some of the hotter nebulæ contain this ultra-elemental matter the eye will not discover it, and the air around the earth is too absorptive for these higher rays to penetrate it and reach us. A "fire mist" of primordial matter must remain invisible until some part cools sufficiently to form aggregations which we call elements, which are, perhaps, only extremely stable forms resembling in stability most of our known compounds at near absolute zero.

Admit the possibility of the view here expressed as a speculation merely, and it follows that there may be stars so hot interiorly as to possess only an outside layer of elements in the ordinary sense, while further down within them are the black depths which shine only with the higher rays. Our sun has a low density, and if its interior, not subject to radiation loss, be of very much higher temperature than its exterior cloud of ordinary elements, a rift in the cloud might let out Röntgen rays which would produce electrical disturbances in the earth's outer atmosphere.

Again, the mystery of the sun's supply of heat would be in part resolved. The heat given out in the formation of ordinary chemical compounds may be relatively very small compared with that yielded during the condensation of the ultra-elemental matter assumed, into ordinary forms called elements under very powerful chemical or electrical forces. One can then conceive of a real photosphere surrounding the sun and begin to understand the meaning of those tremendous outbursts of activity connected with prominences and spots. Ordinary elementary forms arising by combination and cooling in the outer solar layers would precipitate themselves into the hotter dark interior to be violently decomposed, and this would occur over and over again until the interior temperature was too low for it. Should the action become rythmic we may begin to understand sun spot periods or stellar variability.

These ideas are not scientific in the limited sense; they are the result of imagination allowed free scope in dealing with imperfect data. The whole fabric must stand or give way according to fitness in the light of advancing knowledge of real facts. The history of science and invention shows that progress often depends upon a fortunate leap in the dark, and that no harm can come from consideration of many suggested hypotheses in a field where so little is known. To forewarn is to forearm, even if the final result is to expose a fallacy.

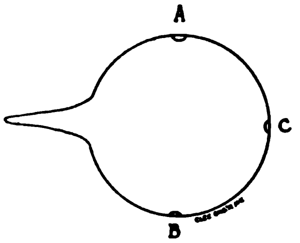
If the writer succeeds in drawing attention more than ever to such a fruitful field of research as the Crookes phenomena furnish, he will be satisfied. The conviction cannot be escaped that we have in them the opening of a new era in physical science, an extension of limits, a new chemistry, perhaps.

THE EFFECTS OF ROENTGEN RAYS UPON A BEAM OF LIGHT.

BY FRANCKE L. WOODWARD.

SOME experiments were recently made by myself in relation to the effect of Röntgen rays upon a beam of light projected through a vacuum and as the results appear to be of much interest, I send herewith an account of the same.

The accompanying illustration shows the form of tube used in carrying out the experiments. The tube is entirely coated with black paper except at the points A, B and C, which are small circular openings one-half inch in diameter, the tube being exhausted to the highest state of vacuum. A calcium lamp was used so covered with heavy black paper that only a circular beam of non-actinic light one-quarter of an inch in diameter was projected from it. With the addition of a good Crookes tube, this apparatus is all that is required to proceed with the experiments, which must be conducted in a perfectly dark room. The Crookes tube must also be covered with black paper to prevent any visible fluorescence.



Now, upon projceting a beam of light from the calcium lamp upon the vacuum tube at the opening, B, so that it shall emerge from the opening, A, and fall upon a screen conveniently arranged, it will be found that the beam of light coming from A will not have more than one-twentieth the intensity of the same beam entering at the opening, B. On viewing the interior of the tube through the opening, C, the beam in crossing the interior vacuum is almost imperceptible. It would seem from this that if the vacuum were perfect and no diffusion or reflection were possible, no light would emerge at the opening, A.

Now, performing the identical experiment again, but having a powerfully excited Crookes tube focused upon the vacuum bulb, it will be found that the beam of light emerging at A, will have almost the same intensity that it has on entering at B. Repeating the experiment with tubes of different exhaustion, it will be found that the intensity of the emerging beam of light will be inversely as the degree of exhaustion, except when the Röntgen rays are focused upon the vacuum tube. This would seem to strongly support the theory of Tesla, who has claimed that the Röntgen rays are moving particles projected, for when the vacuum tube is traversed by the X-rays or rapidly projected particles, the beam of light is better able to traverse the intervening space and certainly shows a remarkably interesting relation between the Röntgen rays and ordinary light.

It has been suggested to me that no artificial means can produce a more perfect vacuum than that existing in interstellar space, that this affords a practically non-resisting medium for the transmission of light, and that it is inconceivable how any vacuum, unless it were a vacuum space in the ether, could afford the slightest absorption to a beam of light.

The above suggestion has seemed true to me until my recent researches have led me to believe otherwise, and my results are confirmed by Prof. M. B. Snyder, of the Franklin Institute, who recently, in an address before that body, is quoted as saying: "There is nothing in the Röntgen ray differing from what we call an electromagnetic ray. In time it will be possible to refract and reflect it and do anything with it that we can with light. Possibly what we term light in our atmosphere is nothing more than a transformation of energy out of the cathode rays shot off by the sun itself. Possibly light does not come from the sun at all." He believes that the vibrations known as light are generated in the atmosphere. Were we to go up beyond the atmosphere, we would not see the sun at all.

ELECTRIC LIGHTING

A 250 C. P. INCANDESCENT LAMP.

BY JAMES E. CRIGGAL.

NOW that electricians are interested in high voltage incandescent lamps it will not be out of place to call attention to a form of incandescent lamp that would be very desirable at present.

To any one who has had experience with incandescent lamps of different candle-power and has noticed the lasting qualities of each, they have no doubt noticed that a 50 c. p. 50-volt lamp will last very much longer than the ordinary 16 c. p. lamp. If we take the same thickness of material that a 50 c. p. 50-volt filament is made of and increase the length five times, we have a filament that will take five times the voltage to bring it to incandescence and it will give five times the candle-power, or 250 c. p. at 250 volts. The cost of platinum will be the same as the 50 c. p. 50-volt lamp; the only difference will be a longer filament and a larger bulb. The arrangement of such a filament in a suitable bulb is not a serious problem.

Now that there are methods known to take all of the residual air out of the bulbs and also a process of taking all of the gases out of the filaments, there will be less danger of sparking across the terminals, and there is no reason why such lamps should not be on the market. There is no doubt that such a lamp would give an ideal method of interior lighting of stores, store windows, churches, and with properly designed waterproof sockets, street lighting.

Although the cost of such lamps to maintain would be perhaps a little more than arc lamps, they will give much better distribution of light.

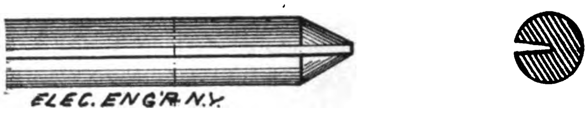
They are free from sparks flying round, and they will do away with that bugbear, trimming of arc lamps, which is sometimes a nuisance.

THE FOOTE SLOTTED ARC CARBONS.

TO prevent the traveling of the arc around the circumference of the carbon, the device of coreing it with a softer carbon mixture has been successfully introduced in practice, and cored carbons are now considered indispensable where the highest perfection of arc lighting is sought for.

With a view to obtaining the same result of maintaining the arc constantly at the center of the carbon, Mr. Theodore M. Foote, of Chicago, has hit upon the idea of slotting the carbon over its entire length, the groove penetrating to the center, as shown in the accompanying illustrations.

It is ascertained in the practical use of these carbons that the arc interval shifts within a very materially circumscribed path of travel, owing to the ever-present cut-out or notched portion maintained by the groove, in the circular edge of the crater, and instead of moving continuously about the circular path of the edge of the crater the arc interval simply shifts alternately back and forth between the two sides of the groove about the edge of the crater. With this limitation of the shifting movement of the arc interval it is demonstrated in practice that the shadows do not form, since the one side does not, under these conditions, become of such a relative height as to cut off the rays.

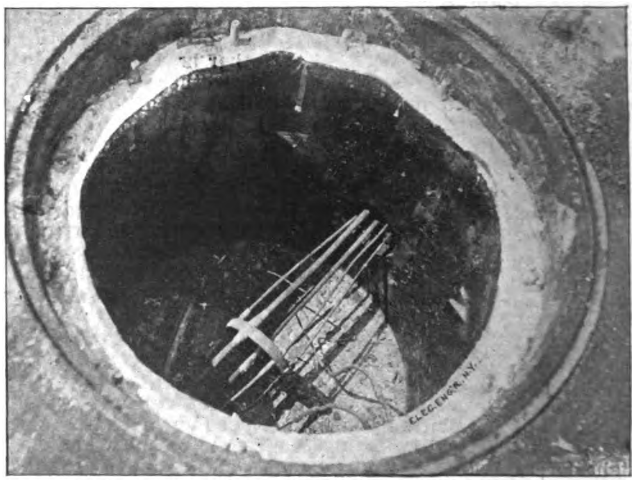


THE FOOTE SLOTTED ARC CARBON.

THE CUMMINGS CONDUIT AT NIAGARA FALLS.

BY ORRIN E. DUNLAP.

THE Niagara Falls Hydraulic Power and Manufacturing Company, of Niagara Falls, have found the Cummings Conduit Company's system of carrying bare wires underground very serviceable. At Niagara Falls the conduit is laid under the asphalt pavement on Falls street, the length of the conduit in use being about three-quarters of a mile. The conduit as there laid consists of an iron pipe, in 20-foot lengths, containing five ducts. The best standard lap-welded pipe is used, dipped in an insulating varnish. The ducts are made from the best kiln-dried wood, also in 20-foot lengths and boiled in oil to thoroughly saturate the wood and kill the fiber. After a group of ducts has been placed in the pipe an insulating compound is forced in, completely filling the space between the ducts and the inside surface of the pipe.



CUMMINGS CONDUIT AT NIAGARA FALLS.

At Niagara Falls six ducts are used, and through them are run two circuits of 2,000 volts each, alternating current, and one circuit of 500 volts, direct current. The current so transmitted is used for light and power purposes. The conduit starts in an alley between the Riverway and Prospect street and extends up Falls street to Third street, crossing Falls street five times to provide outlets. The outlets consist of pipes containing four ducts. Manholes are placed at convenient distances, the number in the length mentioned being six, each about 3 feet in diameter.

The accompanying engraving shows the interior of one of these manholes and the bare wires passing through it, also the wires leading to one of the outlets. The manhole junction boxes are of iron and have two covers, the outer cover being flush with the street pavement, while the inner cover is bolted against a rubber gasket, preventing water or moisture from entering the box. The service over the lines in this conduit has been continuous night and day for two years, and it has been found efficient in every way. Supt. Frank G. Lott, of the Niagara Falls Hydraulic Power and Manufacturing Company, speaks well of it.

SOME THINGS ABOUT WIRING AND WIREMEN.—I.

BY S. H. SHARPSTEEN.

To do electric wiring successfully is one of the severest tests of the skill of a workman. When the designer sets to work to plan a dynamo, he has much data to work from, everything is carefully considered and once the patterns are out, the first lot of machines running successfully, the careful mental supervision is over and thousands of machines may be made with but the ordinary shop supervision. But such is not the case with wiring; every job has some new condition about it, the obstacles that are ever coming up are legion and yet there is so little written about it. The fact is that the wiring business does not get the consideration that it should, the execution of the work is often left to the man not skilled in the art of wiring, but full of ingenuity which he uses to fool the fire underwriters, architects and owners of buildings. The way in which some wiremen will get misfits to go is surprising, and the result is that very much of the wiring done is botch work. Go where you may, aboard an ocean-going steamer, in a large office building, a mansion, an electric light station or a factory, the same thing prevails. After passing through the steamer or building there are many things that would meet the eye that are in a tumble-down condition. On asking the engineer in charge he will tell us of something that was not put in properly and had to be "pulled down."

If there is a person who thinks that this state of things does not exist, let him visit some of the large State hospitals and listen to the tale of woe as told by the person in charge of the electrical work. Oftentimes said person will wonder why he is not in a ward with the "loons," as he calls them. This condition of things should not exist and if the wiring business had the consideration that it deserves it would not. Some persons will say that if the price was paid the work would be good; this is not true, since the State has paid out enormous sums of money for work that is not good engineering. The one great fault is that architects, engineers and inspectors have not got the proper knowledge of the work.

The writer might cite an example: He had charge of some work in a number of State hospital buildings. There were two inspectors on the job; one was local and the other was from the Capitol and we called him the State inspector. These men were employed, one by the local hospital board, the other by the State, and not by the fire underwriters. The reports of both inspectors used to get into the hands of the local board of trustees. The State inspector looked over a building and reported some incandescent wiring as very poorly done; wire running through air shafts tied up with strings, etc. The facts of the case were, no work had been done in said building and the wiring passed upon was some that had been done years before and was used in the fire alarm system. All the wire used for lighting was rubber-covered. This fire circuit was a cheap weather-proof. There was hardly a thing about the work to suggest that it was to be used for lighting purposes. A detailed account of what happened during the completion of this contract would read like a novel in the hands of a good writer.

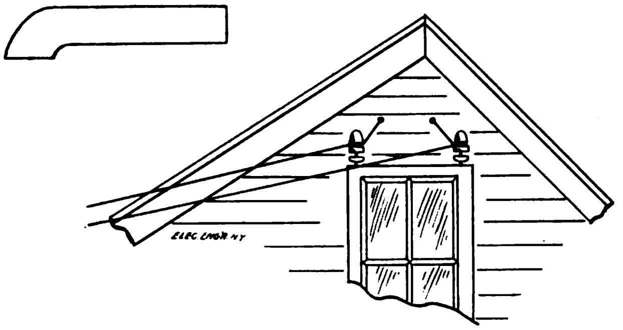
We often hear it remarked that the young man who has learned the carpenter trade is good timber out of which to make a wireman. The reason is this: A wireman has much carpenter work to do. Many old buildings have to be rewired, and there is much cutting and planning that only a carpenter can do successfully. How to use a brace and bit, especially in getting holes through woodwork that is full of nails, and have the holes parallel, is a job that taxes the skill of the best of wiremen, and as a person looks at the entrance wires where the service wiring is above ground, he will see many things that tell of the use of the brace and bit in the hands of an amateur.

Many wiring firms have carpenters employed with their gangs to do the carpenter work, but the man that wires a building quickly and gets the money out of the job is he who has the knowledge of the carpenter and wireman combined. A carpenter will see things one way and the wireman another, and in trying to get their veiws reconciled much valuable time is often wasted.

The young wireman should become thoroughly conversant with the use of the mitre box as a good job of moulding work is another evidence of the skill of the carpenter combined with that of the wireman. After long practice many wiremen will guess at how to cut a mitre and make a good looking job from the outside, but the use of the box and good solid joints with as little fitting with the knife as possible is preferable.

Possibly the writer is safe in saying that the wiring jobs done in the average dwellings are not safe, although the best grades of rubber wire and porcelain are used and the workmen do the work in accordance with the latest rules of the underwriters. We will graphically wire a dwelling and give reasons why we do certain things and see where we differ from old customs.

The first question that comes up is where to enter with our service wires. In this case we will come in at the back of the house in the attic. Two neat iron brackets on which are mounted a good grade of glass insulators, iron, well painted to keep from rusting, will be placed up near the roof in the gable, each wire equally distant from the center of gable and about 2 feet apart, if the service wires are not too long and can be drawn up tightly. If the service wires are long, 3, or even 4, feet would be better; in this case the wires would be so far apart that they could not get crossed or "kiss" each other when the wind blows. Over the insulator brackets, and about 8 or 10 inches each side of the center, put holes for the porcelain entrance tubes; some contractors use a tube like Fig. 1, but it seems that they are uncalled for. The writer would recommend a straight tube, but makes sure to have the hole slant out. The service wire is brought from the porcelain, tied on the glass and put through the porcelain tubes.



FIGS. 1 AND 2.

Now if one end of the tube is turned down, like Fig. 1, and the service wire is large, there is a difficult time in store to get the wire through the tube, but if the tube is straight the wire goes through into the building easily. Another bad thing about a tube like Fig. 1 is that in case the service wire is heavy and should come off the glass the tube is more apt to break from the pull on the crook by the service wire where it enters the tube. Each entrance tube should have a ¼-inch wall, should be well fastened in its respective hole and project at least 3 inches from the building on the outside; the head should be inside.

Inside the building on a smooth board painted with insulating compound we place a main block amply large to carry the current for the whole building. In this case we will consider that we are going to wire the building for 200 16-candle-power lamps; hence, the main block should be of at least 100-ampere capacity. The wires sticking into the building are tied upon appropriate sized knobs to hold them in position and then the ends are placed securely into the main block.

Now the outside of the building should look like Fig. 2. From the glass to the tubes the wire should be drawn up tightly, so that it cannot be bent against the building by a painter's ladder or any similar cause. Some contractors possibly would put the transformer on the building, if alternating current was to be used, for they reason that it would save running a heavy service wire from the pole line, but we think that the best practice now puts the transformer on the pole and the fire underwriters demand it.

We get in the gable, if we can, to save the wires from ice and snow falling on them from the roof in winter. We put good strong brackets on the house (and not the wires directly into the tubes), to hold the wires securely and to save the tubes from too hard strain in sleet storms, and we put the porcelain tubes above the glass so that all water will run away from the holes in the building.

RECENT PROGRESS IN ARC LIGHTING.—III.

BY PROF. ELIHU THOMSON.

(Concluded.)

THE distribution of light from an alternating-current arc with vertical carbons, owing to the fact that the chief light source—the positive crater—is on the upper and lower carbon alternately, is both downward and upward.

A moment's consideration will show that under no circumstances can an alternating arc give out as much light for a given expenditure of energy as does a continuous-current arc for the same expenditure. The light comes mainly from the positive crater, whose temperature and consequent luminosity is limited by the vaporizing point of carbon. The positive crater from which the current passes to the arc is much larger and much hotter than the negative spot on the opposite carbon receiving current. If, now, there is a rapid interchange or reversal of current and dead points or zeros between the reversals at each alternation, the positive crater has to form anew upon a surface, which, while negative, was, on the average, far below crater temperature, having cooled during the time it was negative, and during the zero or period of extinguishment. It results from this that the average temperature of the light-emitting surface of carbon in an alternating arc is below that of the vaporization temperature of carbon, and the emission of light consequently lessened. It is known that the light emitted from a hot surface as temperature rises, increases far more rapidly than the temperature or total radiation.

The shape of the wave of current has a great influence on the conditions of temperature just pointed out, and the rectangular wave must necessarily approach in its efficiency more nearly that of continuous currents than a peaked wave with longer zeros.

The use of single arcs across alternating constant-potential mains requires only that the lamp mechanism be operated by variations of the current passing the arc. Hence, an electromagnet in series is used to lift and feed the carbons, or sometimes the expansion of a high-resistance wire, traversed by the lamp current, has been applied for the same purpose, as in the "Kester" lamp. The electro-magnet is open to the objection that its action is so instantaneous as to be liable to provoke chattering at starting. In the use of a hot wire the objection of chattering at the start is overcome without difficulty, and the wire is noiseless in its action; but it demands that considerable energy be wasted in it, and hitherto the temperature at which the wire must be run to secure sensitiveness of feed or rapid heating and cooling, following variations of current, has been such as to endanger its permanence or cause it to oxidize. The writer obtained, a considerable time ago, a much better result by using the hot-wire principle. but variably shunting it by a set of contacts controlled by a small electro-magnet in series relation, which addition imparted greatly increased sensitiveness, while the slow start given by the hot wire was still secured.

It is well known that in practice an alternating-current arc often starts readily with new carbons, the trouble of chattering appearing when a new arc is to be started with carbons which had before been heated or used. This difference is owing to the fact that in the latter case the high temperature of the arc had driven out the gases and volatile materials, which, as present in the ends of the new carbons, facilitate the formation of flame or lower the resistance of the arc at starting. By dipping the ends of the used carbons in a solution of some salt for a moment, the required volatile matter may be furnished to them so that they will start as readily as the new carbons.

With the open-air arc a comprehensive set of tests made under the writer's supervision disclosed the fact that various makes of carbon gave widely different results. It was found that the length of arc or separation of the carbons for a given potential was, under equivalent conditions, quite variable, and the curious fact was noted that with some makes of carbon the variation of arc length with variations in the potential of the circuit supplying the lamp were much less than with certain other makes. Some gave excessive variation of arc length with moderate variations of potential at the arc, while others gave only moderate variations of arc length for considerable variation of potential at the arc. Of course, the latter are far the most desirable carbons for practical use. It is too early to predict what part the "inclosed" alternating arc may play in the future art of arc lighting, but it probably will find a considerable application.

It may be well to add to the present paper, which has grown to unexpected length, a statement concerning the results arrived at by innumerable tests of the different types of arcs and arc lamps under conditions resembling those of practice, with a view of ascertaining their lighting values. These tests have been embodied in comprehensive reports by Mr. Jesse Coates, of the testing department of the General Electric Company, at Lynn, and the tabulated results might easily furnish material for a lengthy discussion. They embody complete series of measurements of candle-power in various directions, and curves of the same for each kind of arc or condition of surrounding globe, together with mean spherical and estimated useful illuminating intensities. The methods of measurement cannot be detailed here, but are such as, in the writer's judgment, can be relied upon to give comparative figures. Moreover, the mean of many observations is, in each case, taken for comparison and plotting of curves.

The purpose here shall be to state, in a general way, some of the results obtained.

It is well known that the larger the arc, or the larger the current in it with a normal voltage, the more efficient is the light production. The energy is more effectively converted into luminous waves, so that the watts per candle would naturally be less with a twenty-ampere arc at 48 volts than with ten amperes flowing. Measurement shows that where, with continuous current, the same brand of hard carbons is used of diameters varying approximately with the current strength, naked arcs, with ten amperes and 48 volts, may take for each mean spherical candle-power 1.2 watts, while arcs of seven amperes and 48 volts require 1.4 watts.

The use of a cored upper carbon appears to raise the efficiency to a moderate extent, probably because the arc may be maintained at a voltage somewhat less, as at 42 or 44 volts. The use of a clear globe surrounding the arc loses 10 to 12 per cent. of the light, while alabaster and opal globes lose from 45 to 65, according to their thickness and the specific absorptive power of the glass. Naturally, since an inclosed arc, consuming approximately the same energy in watts at the arc as a ten-ampere open arc, will have a current of only about seven and one-half amperes, the efficiency would be expected to be less. Measurements show, after a run of 102 hours, and per each mean spherical candle-power of a four and three-quarter ampere, inclosed, continuous-current arc with clear inner and no outer globe (½-in. carbons), an expenditure of 1.94 watts at the arc. If the energy expended in the lamp branch be taken as the true expenditure, that lost in resistance is added to that of the arc, and the watts per candle increased accordingly. A similar loss is, of course, experienced with naked or open arcs on constant potentials, owing to resistance being used in series. The result given above, or 1.94 watts per candle, is at the end of a long run of 102 hours, but with a clear inner globe. Inclosed arc lamps with clear inner and clear outer globes are not satisfactory, and, in fact, for good results of uniformity and diffusion, a slightly opal inner globe is needed. Those now known as alabaster" are well suited to the purpose. When these are used, the watts at the arc per mean spherical candle-power will, at the first part of a run, range about two watts, increasing seriously only toward the very end of the run. While it may seem that the watts per candle are higher than might be expected, yet it must be borne in mind that, in all inclosed arcs, the current is relatively small and the potential high for a given expenditure of energy, and this acts in a double way to lower the efficiency, as not only the crater emitting light is smaller, but a large part of the energy goes to sustain the arc flame, which is long, while, also, the absorption of light by the surrounding glass is not to be neglected. No construction of lamp, regulation or adjustment thereof can get rid of the inherent properties here pointed out. Nevertheless, it is true that the character of the light, both of the open or exposed arc, and of the inclosed arc, is such as to make it very desirable as a substitute for daylight and for many cases of use. The fact that the light is shed mainly downward by continuous-current arcs results virtually in an addition to the efficiency and economy of the light; thus, if the light emitted downward be considered as alone useful, the expenditure per mean useful candle would, with naked arcs, fall to about one-half a watt, and with inclosed arcs, to from one to one and one-half watts at the arc.

With alternating arcs the conditions are different, since the light is sent up and down equally. By a reflector placed above the arc, a considerable fraction of the light which would often be lost upward is sent downward to increaese the effectiveness; thus, a sixteen-ampere, 25-volt, naked alternating-current arc used, per mean spherical candle, 1.49 watts, or for mean useful below the horizontal, 1.12 watts, which was reduced to .8 to .9 watt, when a porcelain reflector above the arc was used. For the same causes that necessarily reduce the efficiency of an inclosed continuous-current arc as compared with the uninclosed, the efficiency of an inclosed alternating arc falls below that of the open arc with similar currents. The watts at arc per candle will be found, per mean spherical candle, to be, under the best conditions, about two watts, increasing toward the end of the run, owing to obscuration of the inner globe and other causes. No reflector or deflector can be used with much effect with the inclosed arc, so that the mean useful is but little different from the mean spherical candle-power.

The apparent advantage in economy of the continuous-current inclosed arc over that with alternating currents is in large measure neutralized by the fact of the former requiring a dead resistance in circuit to give stability to the current, while the latter can be run without it, or, at most, with a reactive coil which wastes but little energy.

Still it must be confessed at the end that the luminous yield is but little better than that obtained in incanadescent lighting. After all, it may be that the whiteness of the light and the daylight effect obtained may be a sufficient reason for the large introduction of inclosed arcs, now that the frequent trimming and attention to the lamp is not needed. Indeed, it may also appear that all the varieties of arc lighting which have grown into importance within the past few years have their own fields of usefulness, and that, therefore, the work spent in developing them has not been labor in vain.

It should be said, in conclusion, that the figures given above and expressing the watts per mean spherical candle, while strictly comparative so far as a study of arc lights alone is concerned, might vary somewhat if the object had been to compare arc and incandescent lights, owing to the difference in color of light, though the variation would not in any case be great.

POWER TRANSMISSION

ELECTRIC MOTORS IN THE NORTHERN PACIFIC R. R. SHOPS.

ELECTRICITY is used to drive all the machinery in the shops of the Northern Pacific Railroad at Edison, in the Far West. Recently the completion of the long distance transmission line between Folsom and Sacramento, Cal., has placed it within the power of the Southern Pacific Railroad to use motors in their shops at Sacramento with most satisfactory results. In their operation the motors have already shown considerable economy over that by the original steam plant which they superceded. The motors are placed in the shops where steam engines had previously been used and the difference between the results obtained apart from the mere question of economy, is marked.

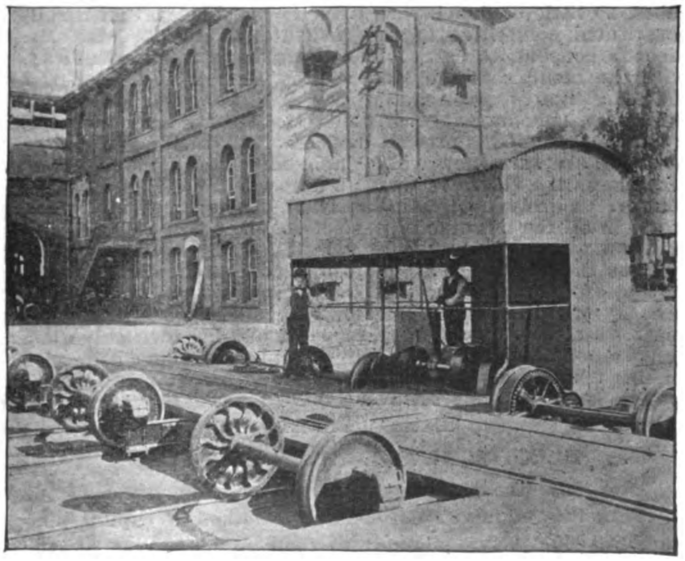


FIG. 1.—TRANSFER TABLE IN SACRAMENTO SHOPS, SOUTHERN PACIFIC RAILWAY.

Three motors are used; the first, a direct current motor placed upon a transfer table used for shifting the locomotives. The motor is a G. E. 800, similar in every respect to those used on the ordinary trolley car, and it is driven by 500-volt railway current from the station. It is so geared that it operates not only the table, but also drives a drum carrying a wire cable, used to haul the locomotives upon the table. This it does with perfect ease, hauling all sizes of locomotives. Instead of taking the current from the overhead wire by means of a trolley, the conductors are laid in an underground conduit and the contact is made by means of a plow running in this conduit. Some fears were at first expressed as to the result in rainy weather, but, although considerable rain has fallen since the installation of this motor, no difficulty has been experienced. The transfer table and motor are shown in Fig. 1.

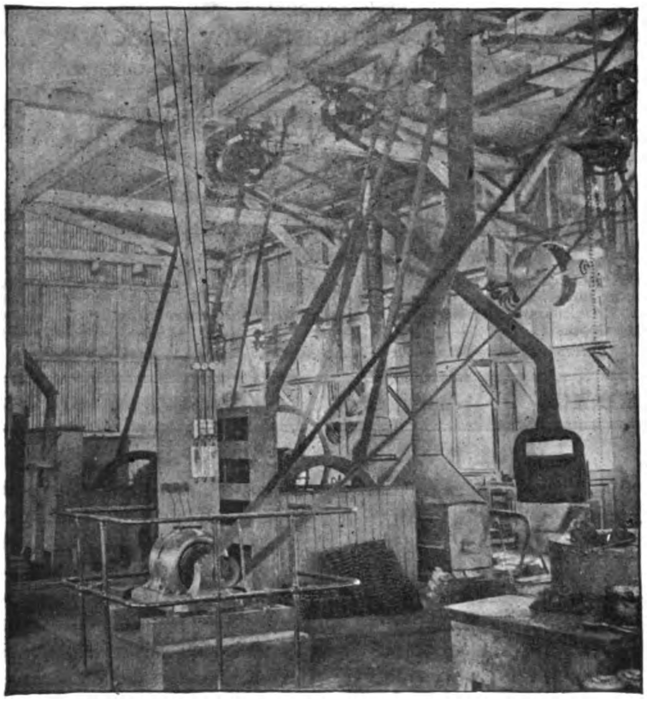

FIG. 2.—INTERIOR SPRING SHOPS, SOUTHERN PACIFIC RAILWAY.

The motor used to operate the machinery in the boiler shop, as well as in the tender shop, is a 50 horse-power motor driven by 440-volt current from the step-down transformers. The machinery in these shops is peculiar in that each machine is provided with a heavy flywheel for carrying it over the sudden shocks which occur in punching and shearing and similar work. For three or four seconds the motor has an excessive amount of work thrown upon it in starting the machine from idleness, and until the maximum speed is acquired. The load then drops to 30 horse-power. Such sudden drops as this are calculated to demoralize motors of ordinary construction; with the induction motor the drop in the load is hardly noticed.

Fig. 2 shows the interior of the spring shop, driven by a 10 horse-power motor; this motor also has to cope with sudden heavy loads. In this shop all the springs—spiral, elliptical and leaf—used in the construction of locomotives, etc., are made and the most difficult piece of work done is the making of the spiral springs, some of which come to the machine as a bar of red hot steel 1¼ inches in diameter. This is placed in the machine, is instantly wrapped around a mandril and it is such work as this that throws for a few seconds an enormous load on the motor. Although it has been in use for some time it shows no sign of strain.

The two motors last named are of the General Electric Company's three-phase induction type, without commutator, collecting rings or brushes. They are driven by 440-volt three-phase alternating current from the transformers, which step-down the 11,000-volt current transmitted twenty-four miles from the generating station at Folsom. This installation is only one of many made since the completion of the transmission from Folsom to Sacramento, which latter city is rapidly becoming dependent on electricity as its exclusive motive power.

[*Entered as second-class matter at the New York Post Office, April 9, 1888.*]

VOL. XXIII. NEW YORK, JUNE 30, 1897. No. 478.

"THE ENGINEER'S" ENTERPRISE.

IN spite of the fact that the meeting of the independent telephone companies closed at Detroit around midnight June 23, when the long new constitution was given out for publication, The Engineer appeared with its report on June 25, devoting several pages to the subject, with editorial discussion, notes of exhibits, and other features of interest. This was several days earlier than any of the other electrical papers, some of whom were not even in attendance at this momentous convention. We are glad to know that the enterprise of The Engineer has been highly appreciated at this juncture, when so much importance is attached to the subject of independent telephony.

A TELEPHONE FIGHT PREPARING.

ALL who have read our report last week of the important meeting of the independent telephone interests must, we think, agree with us that a formidable front has suddenly been presented against the Bell Company, and that the opposition has assumed in a very short time an aspect of activity, strength and belligerency that few expected. Indeed, the action of the United States Supreme Court in declaring that the American Bell Company ought to have its belated Berliner patent has inflamed and intensified a great deal of latent hostility; and so far from being intimidated the opposition gives every sign of being anxious for the fray.

Probably opposition to a great monopoly never before rallied so big a force as this of 1,200 new companies with many more organizing. By the time the meeting ended last week, 50 of them had signed the new constitution—"the declaration of independence,"—and all of them realize that the larger the number of accessions to the ranks, the less the burden on each of necessary litigation will be.

As to the outcome of the fight, it can only be regarded from the standpoint of speculative prophecy. If the American Bell Company were to buy up the whole existing outfit, makers and users, there would be others at once. And as to infringement damages, a curious parallel may be inspiring some of the courage of the opposition. Perhaps, on the whole, a patent has never been better sustained than that on the Edison lamp. Yet at one time, there were about 1,200 or more Thomson-Houston and other companies using incandescent lamps in direct violation of the Edison lamp patents. If any of those opposition companies has ever paid a cent or is ever likely to do so, we have still to be informed of the fact. It is true that recently some of the manufacturers have got together and have agreed to work under certain other patents, but the field is still an open one and never more so than to the new lighting companies as they spring into being. The treasure poured out to sustain the Edison lamp patents was spent in a far more righteous cause than that of the bifurcated Berliner patent, but there is absolutely nothing to show for it, and the thousand infringing companies, if they infringed, are none the worse for their long immunity from any kind of payment. We are not now expressing any kind of approval or disapproval of those bygone events, but simply stating the notorious fact. The interesting question now is whether the Bell Company, magnificent as all its resources of generalship, legal talent and finances are, can make any better showing.

THE GLAD HAND AND THE MARBLE HEART.

WE note that The Electrical Review returns to the apparently pleasant task of throwing cold water on the work and aspirations of Mr. D. McFarlane Moore in vacuum tube lighting. Far be it from us to deny to our contemporary its iconoclastic pleasures; but, whereas it has heretofore confined itself to glittering generalities, its last utterance gives some glimpse of what its opinions are based on, and the public will be glad to be enlightened. Our contemporary explains itself as follows: "Now when we learn that vacuum tubes operated with Mr. Moore's devices take from eight to ten times the energy that ordinary incandescent lamps consume for the same amount of light, and, what is more, that the process by its very nature, is unavoidably connected with such inefficiency, even though the devices attain ideal perfection, we cannot, even to honor the opinion of the emotional editors of our contemporary, though it would give us much pleasure to do so, attach to such efforts the commercial value they would give it." As to the emotional attributes of the editors of this journal, that is aside from the question, though we confess that we prefer to extend the glad hand of encouragement to the struggling inventor, rather than to chill him after the style of our contemporary, with the coldness of the marble heart. But, whence or from whom, we would like to ask, does our contemporary "learn" that Mr. Moore's devices take from 8 to 10 times the energy of the ordinary incandescent lamp? This is most valuable and important information, if true. Certainly, Mr. Moore has never made any such statement of the efficiency of his system, so that it must emanate from "The Review's" own personal experiments. As a matter of fact, Mr. Moore denies absolutely the truth of our contemporary's assertion, and we think that in justice to both Mr. Moore and its readers, "The Review" ought to give the data of its information. Let us have the truth above all and by all means. In this connection, we beg to recall to our contemporary's recollection that when, a year ago, one of the editors of The Engineer, before the American Institute of Electrical Engineers, mentioned the power consumed by Mr. Moore's tubes, so little credence was given to his figures, that a self-constituted committee of the Institute undertook, with Mr. Moore's consent, to carry out its own tests in its own way, with the result that the Moore tubes showed up even better than the figures given before the Institute. Our contemporary very encouragingly foretells the speedy abandonment, by Mr. Moore, of his present devices. And what of it? If he does, we are sure they will be abandoned for something better, just as the vibrators were an antecedent for the improved rotator. Surely no great invention was ever given to the world in all the minutiæ of perfection. It is this blindness to, or, shall we say, ignorance of, the philosophy of history, that disarms the criticisms by our esteemed contemporary. As a matter of fact, nothing that our contemporary or ourselves can say will change by one iota the status of Mr. Moore's deeds. Mr. Moore will have to work out his own salvation, and we hope and believe he will do it; but we don't believe in making the task of the honest worker and inventor any harder than it is by jumping all over him.

ELECTRICAL EXECUTION HORRORS.

IF the philanthropists upon whose recommendations New York State adopted the electrical method of capital punishment, could have pictured to their minds some of the sickening scenes which have been enacted since the law went into effect, we doubt whether they would have so strongly championed electricity as the life extinguishing agent. On several occasions things have gone wrong with the apparatus at the critical moment, and only last week again, it required five separate shocks to kill a miserable convict in Auburn prison. The five shocks were necessary, owing to the imperfect contact. The delicious smell of burning human flesh was quite distinct in the death chamber. This incident reads more like a chapter from the damnable days of the Inquisition than a tale of the end of the nineteenth century; yet under the law as it exists in New York State such horrible scenes are likely to occur at any time. To insist that such a method of execution is the most humane that can be devised is simply ridiculous, and it is high time that some genuine humanitarian society should take up the subject with a view to removing this stigma from New York. One of the very strongest arguments put forward by the sponsors for the electrical execution law was the alleged absolute certainty of the electrical method. Yet this very feature has been again and again proved to be lacking. And as to the alleged painlessness after the first shock, hundreds can bear witness to the fact that a shock can be a prolonged agony of the most excruciating kind. Unfortunately New York's example has recently been followed by Ohio, but it is earnestly to be hoped that no more States will adopt this barbarous, medieval law.

ELECTRICITY IN WARFARE.

RECENT occurrences in Europe have brought out very clearly the growing use of electricity in warfare. Naval experts at Kiel have been testing the practical uses of dragon-shaped airships or balloons, which may be put on board vessels for use during naval engagements, and in reconnoitering. Some of the balloons rose 5,500 feet, remaining fastened to the decks of torpedo boats, which were steaming 18 knots an hour, enabling the balloonists to make valuable observations of the stations of vessels at a great distance. The observations made were communicated by telegraph or telephone from the balloons to persons on the decks of the vessels below, enabling them to change the course of the latter accordingly. At the British jubilee naval review last week, the United States man of war "Brooklyn" received great attention; and Mr. Laird Clowes, the naval expert, declared that, as proved by the new ship, England is in the resort to electricity many years behind the United States. That she will remain so is seriously open to question, but credit for our leadership is welcome and must be ascribed to the patient and brilliant work of such men as Lieut. B. A. Fiske, who may be said to be devoting their lives to this subject, in behalf of our navy .

THE TROLLEY AND COUNTRY RETAIL TRADE.

A WRITER in the "Iron Age" speaks of the trolley as a "dangerous feature for the smaller dealers" in hardware, because it enables the farmer, who was formerly tied down to the general local store, to reach easily the larger centers of trade. "It did not pay the inhabitants of small cities to spend $3 to $4 for the purpose of purchasing about the same amount in a large neighboring city, especially when the number of trains was limited, and when it consumed a whole day and well into the night to make the journey. But now the electric car stops at the farmer's door, suburban cars leave every 30 minutes, they carry express packages, and they take much of the local trade to neighboring cities. The small country dealer is the greatest sufferer. He loses his cash customer, and retains those whom he has to carry and who have no ready money. The larger towns gain from the country what trade they lose to the cities, while the cities have nothing to lose." It strikes us from a different point of view. The very fact that the trolley cars deliver express packages should enable the small general store in a village to carry practically a much larger stock than ever before, and to fill many wants that previously were not felt or went unsatisfied because of the distance from market. Besides, accessibility always promotes trade and intercourse, and this ought to be a good thing for the small country dealer, particularly if the trolley brings into his neighborhood a number of residents, earning good weekly cash salaries, to whom the real country was formerly out of reach. Heretofore, the small dealer has presumed on his inaccessibility, and made it an excuse for not handling a number of useful and desirable things. The trolley gives him a genuine opportunity of new life. But if he supinely lies down to die, he will die before he is dead, and someone else will see the modern chances and find a profitable way out.

MUNICIPAL LOSSES AT YARMOUTH, ENGLAND.

ACCORDING to figures given at the last council meeting, the town of Yarmouth, England, is already paying pretty dearly for its municipal electric light plant. The deficiency for the last year and a quarter is $3,650; the deficiency for the previous year was $3,780. The town council begins to wonder whether it is in for a yearly deficit of about $3,500, and how long the public and the modest local treasury will stand it. This is one of those successful foreign plants people are so fond of telling us about.

EDUCATIONAL

MR. J. B. WHITEHEAD.—When the Johns Hopkins University in Baltimore resumes its course of work next fall it will have a new assistant professor in the person of Mr. John B. Whitehead, who at present is connected with the Cataract Construction Company at Niagara Falls, Mr. Whitehead having received an appointment to the position.

MARRIED

NALLY-REDD.

Edward J. Nally, assistant general superintendent of the Postal Telegraph Company, with headquarters at Chicago, was married to Miss Lee Warren Redd, daughter of Captain Oliver T. Redd, of that city, on June 10 at Lexington, Ky. Among those present were Guy E. Paine, superintendent of the Postal Telegraph Company at Kansas City, who for several years was manager of the Postal Company in Chicago; C. M. Baker, superintendent of construction, Chicago; F. J. Loesch, H. L. Childress, superintendent at Birmingham, Ala.; W. J. Capen, superintendent at Cincinnati; Grenville Howard, superintendent long distance telephone, St. Louis. The happy pair received a silver chest of eighty-three pieces from Postal Telegraph employés. Mr. and Mrs. Nally will return from Europe on the steamer Majestic about July 31, and will make their home at the Virginia Hotel, Chicago.

OBITUARY

EUGENE E. BOGART.

It is with extreme regret that we announce the death of Mr. Eugene E. Bogart, who for some time past has been doing a large business in the field of electric gas lighting apparatus, in New York City, having succeeded his father, Abraham L. Bogart. Few names are so well known in this branch of the electrical arts. Mr. Eugene Bogart was a retiring man, but made a great many friends by his sterling qualities of heart and mind. It is the more distressing that his death is the result of injuries received from an accident, Mr. Bogart having been thrown from a cable car in this city last February. He is survived by a brother, Mr. A. Livingston Bogart, well known as an electrical expert and inventor, and as a contributor to the electrical press.

THE STOCK MARKET

STEADY BUT SMALL GAINS.

While a sturdy confidence now prevails that general trade will be active in the fall, events are moving but slowly in that direction. There is improvement, however, and it is becoming more pronounced out West, just as a few months ago, the East was in the lead. This oscillatory process is to be noted all the time, but the gains are kept and serve as foundation for a further rise.

During last week 35,584 shares of Western Union were sold up to 84¼, and 3,672 shares of General Electric up to 33¼. American Bell telephone on small sales rose as high as 234, and the effect of the opposition movement is certainly not yet apparent in any decline of value.

TELEPHONY AND TELEGRAPHY

AUTOMATIC TELEGRAPHY.—II.

BY P. B. DELANY.

HAVING estimated the speed of the various systems in use in this country—simplex, duplex and quadruplex Morse, and the Wheatstone automatic—the interruptions to working by disarrangements to which they are liable should not be overlooked. With simplex Morse there is practically nothing of this kind. The Morse duplex, however, requires balancing and readjustment from time to time, owing to the inevitable changes in the atmospheric conditions. These difficulties may be said to be quadruplexed in the quadruplex.

There is no data upon which to found an estimate of the proportion of time used in balancing the quad. Since the introduction of constant pressure by the substitution of dynamo generators and storage batteries the causes of disarrangement are due principally to changes of weather, which are always taking place somewhere over long sections. The working margin is not great, and slight changes call for some compensation if efficiency of working is to be maintained. These difficulties are aggravated where repeaters are necessary, first on account of greater area of country, second on account of double balancing required by the two sections intersected by the automatic repeaters. The introduction of the dynamo and accumulators in telegraphy have not been altogether of unqualified advântage. The voltage has been increased to an excessive degree in order to overcome defective insulation. As may be well understood this has affected the electro magnets unfavorably and worked other evils guarded against when chemical batteries were used. At best, the quadruplex is a fickle dependence; indeed it is the opinion of many telegraph managers that the polar duplex is preferable, holding that the increase of facilities does not balance the increase of labor necessary for its operation and the amount of high-class attention required in keeping it going.

With regard to the Wheatstone system, it cannot be questioned that it represents the best efforts of able telegraph engineers and mechanicians covering a period of about thirty years. It would be hazardous to say that anything is finished or beyond improvement, but in electro-magnetic telegraphy the Wheatstone system seems to have reached the limit about twelve years ago when the quick acting relay was relieved of its self induction effects by the condenser shunt.

While the great number of adjustments necessary and the liability of the Wheatstone to disarrangement on slight provocation are serious drawbacks the fundamental obstacle in the way of any further advance in speed or stability of operation lies in the fact of its being electro-magnetic in principle. In it is probably represented the limit of electro-magnetic actuation of normally inert recording devices, or in other words the utmost rapidity with which the lightest and most delicately adjusted armature can be moved with sufficient power and play to make and break a local circuit or an ink line on a moving tape is demonstrated in this machine. It is evident, therefore, that greater speed can only come through a system not using electro magnets for receivers.

THE CHEMICAL AUTOMATIC.

Thus far the only practical receivers of this kind have been founded on the original plan of Bain's use of a chemically dampened tape, which, under the action of the current passing through it, would leave a mark corresponding to the dot or dash sent into the line at the transmitting station. It is needless to follow in detail the development of this brilliant idea. Improvements have been made from time to time by different people, nearly all having been in some respect, at least, an advance on what had previously been done, but all leaving much to be desired for the practical introduction of this method of telegraphy.

It cannot be doubted that had chemical telegraphy received the same assiduous attention from able experts that has been bestowed upon the Wheatstone, it would have long ago reached perfection and supplanted the Wheatstone system. Even now, however, the early drawbacks of the chemical plan seem to have lingering attractions for some among the prominent Morse men, who, doubtless, on account of prejudicial preferences attaching, perhaps naturally, to the old Morse stand-by, are loth to acknowledge the removal of the obstacles which have so long beset the ideal principle of fast transmission. Craft prejudices have opposed innovations in every industry. The sewing machine, the reaper, the type-setting machine and typewriting machine, the trolley, the telephone, duplex, quadruplex and multiplex telegraphy, in fact, every improvement has in the beginning encountered this opposition, but experience teaches that economical methods must prevail sooner or later.

In telegraphy the proof of this inevitable change may be seen in the disposition to compromise before capitulation. Automatic transmission from Morse embossing of tapes, retaining all the idiosyncracies and imperfections of key working is being resurrected from the rubbish of antiquity by a few expert Morse operators, and all for a doubtful gain of possibly ten words per minute over hand transmission, but at the same time retaining the main objection which they themselves advance against perfect dots and dashes, mechanically made, i. e., preliminary preparation of the message. An operator will punch absolutely perfect dots and dashes as rapidly as an operator can emboss imperfect ones on a tape. The regular automatic transmitter will transmit from its perfect perforations fifty times as fast as the makeshift will send from its imperfect embossings, and the chemical receiver will record perfect signals at least fifty times faster than the single current Morse relay, by which it is proposed to work an embosser indenting a tape which must be run through a local circuit for reproduction on a sounder, thus reproducing all the faults of the embosser's manipulation, plus the unavoidable failures arising from the original transmission into the main line from an unstable stencil, and two repetitions, one from the receiving relay into the local embosser, the other from the tape into the sounder circuit. Every expert Morse operator knows that the main difficulty now is to so adjust his receiving relay that fast hand sending will operate his sounder without clipping, sticking or dropping of signals, and that even with the slightest aluminum levers and closest adjustments, it is sometimes extremely difficult to get all that is sent. How this same shaky condition can be made to successfully work an embosser requiring three or four times the power and twice as much play, at a higher speed, is not plain. Besides, this possible gain of ten words requires two additional employés as machine tenders.

The highest Morse efficiency is reached with an expert sender sending direct into the line and an expert sound reader using a typewriting machine at the receiving end. In this arrangement is also comprised the best column printing system. It would be safe to put this combination against any printing system in use or proposed. Indeed, for a particular class of business it is hard to imagine anything better, but for the great bulk of telegraphic correspondence, it is utterly inadequate without a multiplicity of wires.

The latest system of automatic telegraphy employs a three-keyed electro magnetic perforator having but few mechanical parts. It can be worked with one finger and with no more labor than is required for the operation of a Morse key, or it may be worked manually with both hands like the Wheatstone perforator. Owing to the omission of the center row of holes unnecessary either in the perforator or transmitter, the liability to disarrangements is at the lowest. When the punches become dull the frame holding them can be removed and another set substituted in a few seconds. The feed arrangement is so perfect that twenty feet of tape punched with a continuous row of holes may be doubled on itself and each hole will register with the other absolutely. And as but one hole is made for a signal, the labor is light and possibility of failure reduced to a minimum. The cost of this perforator compared with others is nominal. The transmitter has practically no moving parts beyond the roller for drawing the tape.

The impulses are sent into the line by wire brushes connected to the line pressing downward on top of the tape and corresponding brushes connected to the current generators pressing upwards beneath the tape. When the tape intervenes, the circuit is absolutely broken, when a perforation is drawn between the brushes the contact is perfectly made. The edges of the holes keep the ends of the contact brushes bright and clean. There is no chance for gumming or accumulation of dirt. The separation of the contacts is always the same, and the pressure is always uniform. There can be no trouble from arcing, as it is broken and wiped out by the tape.

The speed at which contacts can be made without mutilating the tape is estimated at about 5,000 per second; 2,600 perfect signals per second, or 8,000 words per minute have already been recorded over an artificial circuit of 200 ohms, 3 microfarads, with 110 volts. The tape can be run through the transmitter a hundred times without impairment. Not depending on a feed row of perforations, the tape can be started at any stage without missing or injury.

The receiver, like the transmitter, has no mechanism beyond the tape drawing rollers. The record is made by three steel wires pressing on top of the chemically prepared tape. The ends of these wires are in even line, across the tape. The two outside ones are electrically one, and are connected to the line. The middle one is insulated from the other two, and is connected to earth. The perforated tape has two rows of holes for the signals. All the dots are in the upper row, all the dashes in the lower. The battery contact brush under the lower row is connected to the positive current. The brush under the upper row is connected to the negative pole.

When the letter "A" is sent, a negative impulse is sent and makes a single dot in line of the middle wire of the receiver. When the dash is sent two dots are made on the receiving tape, one in the track of each outside recording wire. All are dots, but all those representing dots being sent from one pole of the battery are marked singly, and all dots representing dashes being sent from the other pole of the battery are marked in duplicate on the received tape. The letter "A," consisting of a dot and dash, appears thus: — =. Letter "B," comprising a dash and three dots, is represented thus: = - - -.

This is the highest economy of impulses and they are all of the same duration in the line and of the same length on the tape. Heretofore in chemical telegraphy dots and actual dashes have been sent all by one current, and recorded as dots and dashes all in one line. Unequal currents in the line displaced the signals, and retardation ran the dots and dashes together at the receiving end, rendering very high speed impossible and translation always uncertain and slow. The tailing or running effect was partially overcome by the clearing effect of self-induction currents in a shunt or derived circuit at the receiving end, but always at the expense of the marking current. With the arrangement described, retardation and its consequent tailing effect may be practically ignored, it being impossible to mistake a dot for a dash, or a dash for a dot.

The continental code is used because it has no space letters. The highest number of consecutive dots in the alphabet is letter H, which has four; the highest number of dashes is O, which has three. Even though the retardation of line was sufficient to run all the dots of H together, it could be easily distinguished by the composite length from S, I or E, which have three, two and one, respectively. If desired a slight clearing current may be used at the receiving station. All the helpful expedients used for other systems may be applied to this if necessary. The principles of operation described render them unimportant, however.

DELIVERY OF TELEGRAMS ON TRAINS.

At the recent meeting of railway telegraph superintendents at Niagara Falls, a paper from Mr. L. H. Korty, superintendent of the telegraph department of the Union Pacific R. R., said:

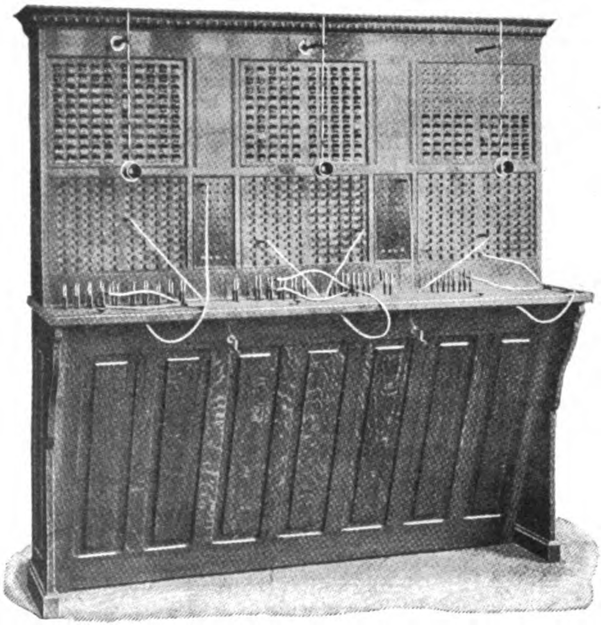
"Many telegrams are received at stations addressed to passengers on trains. These must necessarily be given to the train conductor to find the person. The conductor may be unable to give it personal attention and turns it over to the brakeman to find the owner, but 'Brakesy,' in his anxiety to resume his seat with the woman passenger whom he is entertaining, does not make a thorough search through the train, puts the message in his pocket and the matter is forgotten until the usual claim for damages on account of non-delivery is received. Investigation proves but one thing, namely, that the message was received at the station, but nothing further is on record. The operator claims he turned it over to the conductor of the train, but has nothing to show for it as he failed to take his receipt. The conductor disclaims all knowledge of it. Asked why he does not take receipts for commercial messages delivered, the agent in this case may reply that he does take receipts from everybody except conductors, who usually decline to receipt, and be responsible, for telegrams for parties on trains. Under these conditions there is no certainty that a message will ever reach the owner, or, in case of failure to find him, that the sending office will be notified of non-delivery.

"Most of the irregularities in delivery service exist at the small offices where there is no messenger and not sufficient business to justify the employment of one, the agent performing all the various duties of the station, including delivery of telegrams, and as station employés too often look upon commercial telegraph business as an outside matter, imposing upon them duties for which they receive no compensation, this branch of service is most likely to suffer and be subject entirely to their personal convenience; yet the telegrams received at these thousands of small railroad offices constitute a considerable portion of the whole telegraph business of the country, and, therefore, justly demand our careful attention and individual efforts to improve. Although a railroad company may not share directly in the telegraph earnings, it is compensated in one way or another through its arrangements with the telegraph company, and, aside from the contract obligations properly to handle the telegraph business at stations, there is a moral obligation on the part of the railroad company toward communities and patrons who are dependent upon its employés for this important service. An agent charged up with the tolls on a message delayed or lost through his negligence, generally profits by the experience, and is thereafter usually more watchful of this business; but we should not wait for our employés to be educated in their duties by this means. The paltry amount of tolls refunded to the claimant does not entirely appease his feelings and he will always entertain a lack of confidence in our telegraph service, as well as the service in general at railroad stations."

THE STROMBERG-CARLSON TELEPHONE SWITCHBOARD.

Among the most wideawake and progressive independent manufacturers of telephonic apparatus are the Stromberg-Carlson Telephone Manufacturing Company, of Chicago, This company, as noted by us last week, have carefully worked out and build everything required for local and long distance exchange work, from the receiver to the switchboard.

The accompanying engraving illustrates the standard Stromberg-Carlson exchange board. This switchboard is of the divided type. The company's common return switchboards, wired metallic to terminal pole box, are claimed to be as free from cross-talk as a full metallic board.



The Stromberg-Carlson Telephone Switchboard.

The company asserts that its apparatus is entirely free from infringement of the Bell patents and in an illustrated brochure, just issued, takes up point by point the proof of its claims. We note also some excellent "cautions" intended for prospective telephone investors.

THE PENDER MEMORIAL.

The Marquis of Tweeddale, as chairman of the committee having in charge the International Submarine Telegraph Memorial to the late Sir John Pender, announces that the committee has decided to proceed during the present year with its work. The memorial is intended to commemorate the leading part taken by Sir John Pender in the establishment and development of submarine telegraphy and its extension throughout the world. The committee's work is independent of the General International Submarine Telegraph Memorial to be inaugurated in 1901, and is to take a threefold form. The first of these will be a bust of Sir John Pender, to be placed in some suitable institution and not to exceed in cost £500. Secondly, it is proposed to raise a fund, of not less than £5,000, with which to endow the electrical laboratory of the London University College conditionally on the council's giving to the chair the name of the Pender Chair of Electrical

Engineering and to the laboratory that of the Pender Laboratory. Lastly, the committee proposes to found a Pender scholarship and gold medal in connection with electrical subjects at the Glasgow University. In making its appeal to the public the committee points out that, with the exception of the comparatively small sum to be expended for a bust of the late eminent electrician, the whole of the fund will be devoted to the advancement of technical education. The committee also announces that it has already received subscriptions toward the various objects mentioned amounting to more than £6,000. In this list one-half of the sum is contributed by three telegraph companies—the Eastern, Eastern Extension and East and South African—each of which companies gives £1,000 or more. Among the other subscribers are the Direct United States Cable Company and its staff, £254; the Anglo-American Telegraph Company, £105; J. W. Mackay, New York, £105; the Marquis of Tweeddale, £100; Abram S. Hewitt, New York, £52; the Messrs. Rothschild, £52; Baron Erlanger, £50.

SIGNALLING THROUGH SPACE WITHOUT WIRES.—THE MARCONI SYSTEM.

In our last issue our London correspondent gave some account of the Marconi system of signaling without wires, described by Mr. W. H. Preece before the Royal Institution. We are enabled this week to give some further details of the Marconi apparatus.

Mr. Marconi utilizes electric or Hertzian waves of very high frequency. He has invented a new relay which, for sensitiveness and delicacy, according to Mr. Preece, exceeds all known electrical apparatus. The peculiarity of Mr. Marconi's system is that, apart from the ordinary connecting wires of the apparatus, conductors of very moderate length only are needed, and even these can be dispensed with if reflectors are used.

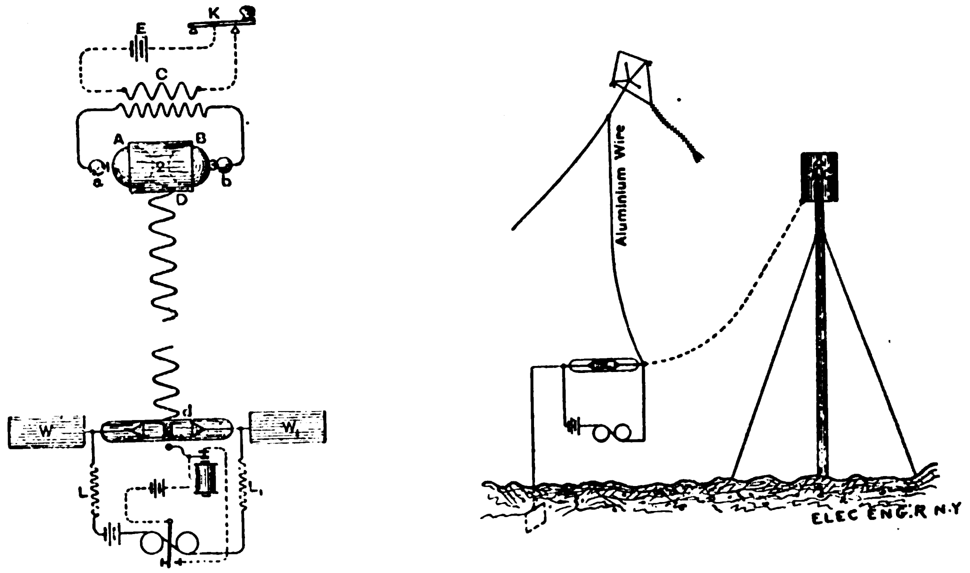
The Transmitter.—His transmitter is Prof. Righi's form of Hertz's radiator, Fig. 1.

Two spheres of solid brass, 4 inches in diameter (A and B) are fixed in an oil-tight case, D, of insulating material, so that a hemisphere of each is exposed, the other hemisphere being immersed in a bath of vaseline oil. Mr. Marconi uses generally waves of about 120 centimetres long. Two small spheres, a and b, are fixed close to the large spheres and connected each to one end of the secondary circuit of the "induction coil," C, the primary circuit of which is excited by a battery, E, thrown in and out of circuit by the Morse key, K. Now, whenever the key, K, is depressed sparks pass between 1, 2 and 3, and since the system, A B, contains capacity and electric inertia, oscillations are set up in it of extreme rapidity. The line of propagation is Dd, and the frequency of oscillation is probably about 250 millions per second.

The distance at which effects are produced with such rapid oscillations depends chiefly on the energy in the discharge that passes. A 6 inch spark coil has sufficed through 1, 2, 3, up to four miles, but for greater distances they have used a more powerful coil—one emitting sparks 20 inches long. It may also be pointed out that this distance increases with the diameter of the spheres, A and B, and it is nearly doubled by making the spheres solid instead of hollow.

The Receiver.—Marconi's relay (Fig. 1) consists of a small glass tube four centimetres long, into which two silver pole-pieces are tightly fitted, separated from each other by about half a millimetre—a thin space which is filled up by a mixture of fine nickel and silver filings, mixed with a trace of mercury. The tube is exhausted to a vacuum of 4 mm., and sealed. It forms part of a circuit containing a local cell and a sensitive telegraph relay. In its normal condition the metallic powder is virtually an insulator. The electric resistance of Marconi's relay—that is, the resistance of the thin disc of loose powder—is practically infinite when it is in its normal or disordered condition. It is then, in fact, an insulator. This resistance drops sometimes to five ohms, when the absorption of the electric waves by it is intense. It, therefore, becomes a conductor. It may be, as suggested by Prof. Lodge, that we have in the measurement of the variable resistance of this instrument a means of determining the intensity of the energy falling upon it. This variation is being investigated both as regards the magnitude of the energy and the frequency of the incident waves. Mons. E. Branly (1890) showed this effect with copper, aluminum and iron filings. Prof. Oliver Lodge, who has done more than any one else in England to illustrate and popularize the work of Hertz and his followers, has given the name "coherer" to this form of apparatus. Marconi "decoheres" by making the local current very rapidly vibrate a small hammer beat against the glass tube, which it does effectually, and in doing so makes such a sound that reading Morse characters is easy. The same current that decoheres can also record Morse signals on paper by ink. The exhausted tube has two wings which, by their size, tune the receiver to the transmitter by varying the capacity of the apparatus. Choking coils prevent the energy escaping. The analogy to Prof. Silvanus Thompson's wave apparatus is evident. Oscillations set up in the transmitter fall upon the receiver tuned in sympathy with it, coherence follows, currents are excited, and signals made.

In open clear spaces within sight of each other nothing more is wanted, but when obstacles intervene and great distances are in question height is needed—tall masts, kites and balloons have been used. Excellent signals have been transmitted between Penarth and Brean Down, near Weston-super-Mare, across the Bristol Channel, a distance of nearly nine miles. (The system was here shown in operation.)



FIGS. 1 AND 2.—MARCONI TELEGRAPHY WITHOUT WIRES.

Mirrors also assist and intensify the effects. They were used in the earlier experiments, but they have been laid aside for the present, for they are not only expensive to make, but they occupy much time in manufacture.

The wings shown in Fig. 1 may be removed. One pole can be connected with earth, and the other extended up to the top of the mast, or fastened to a balloon by means of a wire. The wire and balloon or kite covered with tin foil becomes the wing. In this case one pole of the transmitter must also be connected with earth. This is shown by Fig. 2.

There are some apparent anomalies that have developed themselves during the experiments. Mr. Marconi finds that his relay acts even when it is placed in a perfectly closed metallic box. This is the fact that has given rise to the rumor that he can blow up an ironclad ship. This might be true if he would plant his properly tuned receiver in the magazine of an enemy's ship.

The distance to which signals have been sent is remarkable. On Salisbury Plain Mr. Marconi covered a distance of four miles. In the Bristol Channel this has been extended to over eight miles, and we have by no means reached the limit.

It is easy to transmit many messages in any direction at the same time. It is only necessary to tune the transmitters and receivers to the same frequency or "note." Mr. Preece said he could show this, but was bothered by reflection from the walls. This does not happen in open space. Tuning is very easy. It is simply necessary to vary the capacity of the receiver, and this is done by increasing the length of the wings, W, in Fig. 1. The proper length is found experimentally close to the transmitter. It is practically impossible to do so far away.

MISCELLANEOUS

STORAGE BATTERY ENGINEERING PRACTICE.—XIV.

BY JOSEPH APPLETON.

(COPYRIGHT, 1897.)

STORAGE BATTERIES IN EDISON STATIONS.—Continued.

THE Brooklyn Edison Electric Illuminating Company has one storage battery plant in operation and is installing a second of much greater capacity. The former plant is located at their second district station, being used both as an auxiliary to the generating machinery there, which is only run during the hours of maximum load and as a battery sub-station in connection with the main generating stations in the first and third districts, to which it is connected by means of tie-lines. This plant consists of 160 cells, and has a capacity of 800 amperes for ten hours; 2,000 amperes for three hours, or 4,000 amperes for one hour.

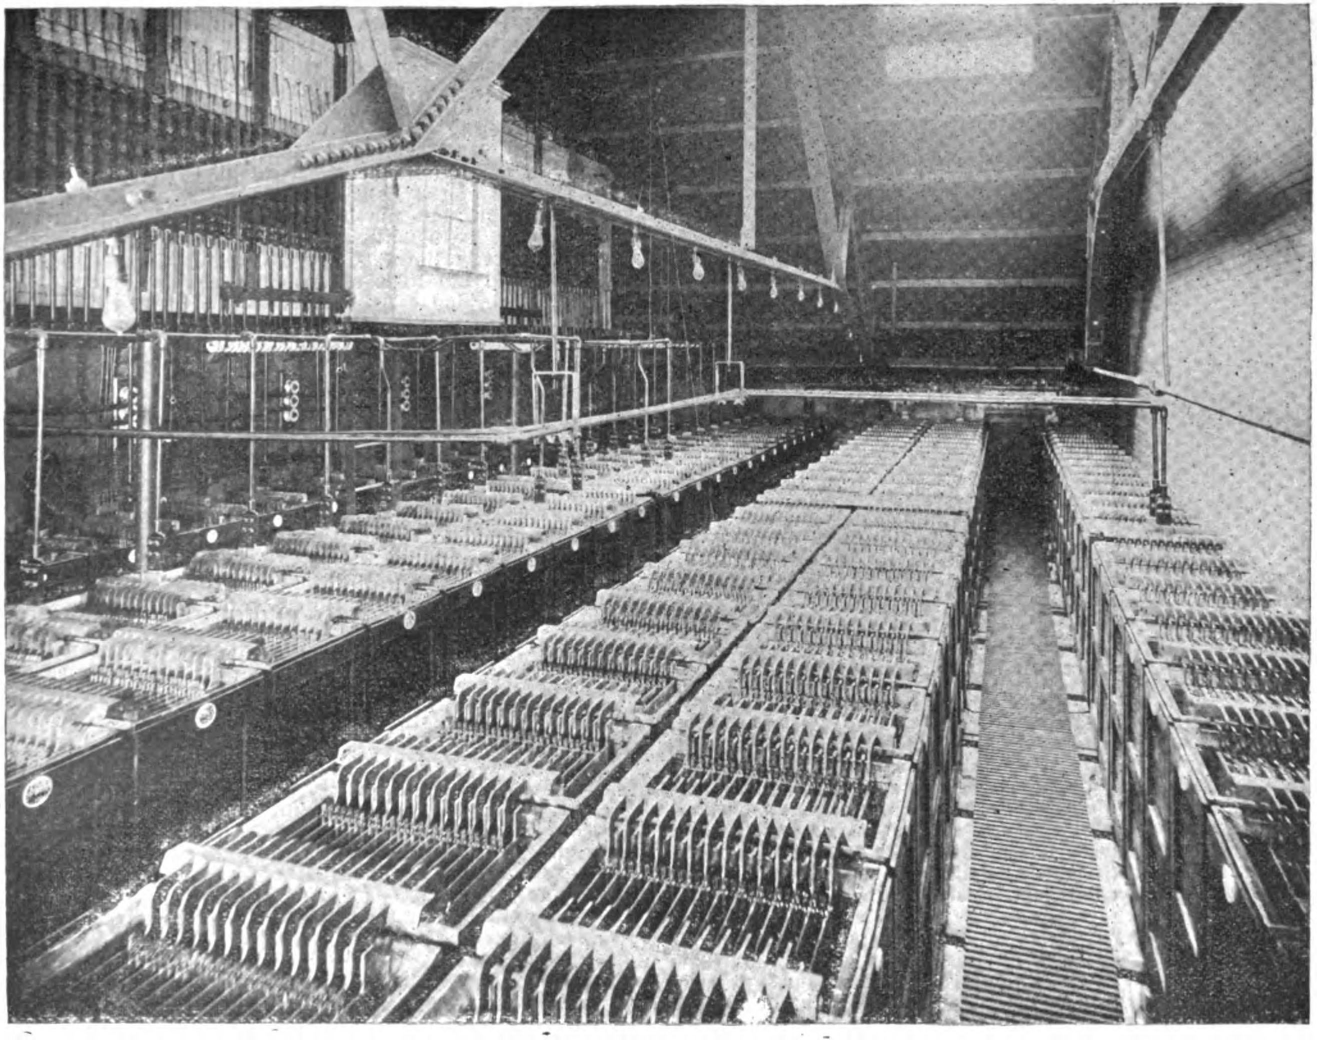


FIG. 59.—STORAGE BATTERY ROOM, SECOND DISTRICT, BROOKLYN EDISON STATION.

Figs. 59 and 60 illustrate, respectively, the battery room, and the cell-regulating switches. The battery is installed in a gallery erected at one end of the station and supported on iron columns. The battery room is partitioned off to prevent the acid fumes circulating through the building.

The cell-regulating switches are located in a small gallery constructed on the end wall of the building, which forms one side of the battery room (see Fig. 59) so as to be in as close proximity as possible to the end cells of the battery, thus reducing the amount of the round copper rod with which they are connected thereto. The thirty end cells on each side of the three-wire system are connected to these switches, so that any number of the cells from 51 to 80 may be used.

The main distributing switchboard is located on the first floor of the building, underneath the storage battery gallery, and all the regulation and control of the battery is effected from this point. The cell-regulating switches are operated by a one-half horse-power Lundell motor connected by worm gearing to the screws; these motors are controlled by special switches placed on the main switchboard, which enable the motors to be run in either direction as desired to cut in or out cells according to the conditions which exist. Fig. 60 illustrates the two cell-regulating switches and motor driving gear for one side of the three-wire system. A novel arrangement is provided for, showing the switchboard operator when the traveling contact brushes of the cell-regulating switches are exactly over the contacts; this consists of two 16 c. p. incandescent lamps placed over each of the motor control switches, and connected so that while the brush is traveling from one contact to another they are in series across the 110-volt circuit, and, therefore, burn dimly. When the brush reaches the position exactly over a contact one of the lamps is extinguished and the other burns at normal candle-power, thereby showing the operator that the brush is in the normal position on the contact and that the motor must be stopped.

In addition to this arrangement there is an indicator with a scale and needle which indicates the number of cells in circuit. The principle on which this works is that of the Wheatstone bridge. A resistance wire is stretched the entire length of the cell-regulating switch and a contact is made on the same by the traveling brush, its position being shown on the indicator according to the relative proportion of the resistance wire on each side of the brush. The scale of the indicator is calibrated in divisions which correspond to the contacts on the cell-regulating switch, and are numbered accordingly.

This method of operating the cell switches from a distance is very satisfactory, enabling them to be placed near the battery, thereby shortening the length of copper conductors, at the same time allowing the control to be effected at the main switchboard where the operator is in touch with the entire system.

As previously stated, this battery is used both as an auxiliary to the second district generating plant during the hours of maximum load, also to carry the entire load in conjunction with a tie-line from the First or Third stations. The charging is done in various ways, depending on the conditions, viz.: From a pair of machines in the Second District station, either with or without a booster; or over the tie-lines from one of the other stations, with or without a booster. This arrangement gives great flexibility to the system and enables the varying load in the district to be carried with a constant load on the lines, and also enables the generating machinery at the Second District station to be run most economically.

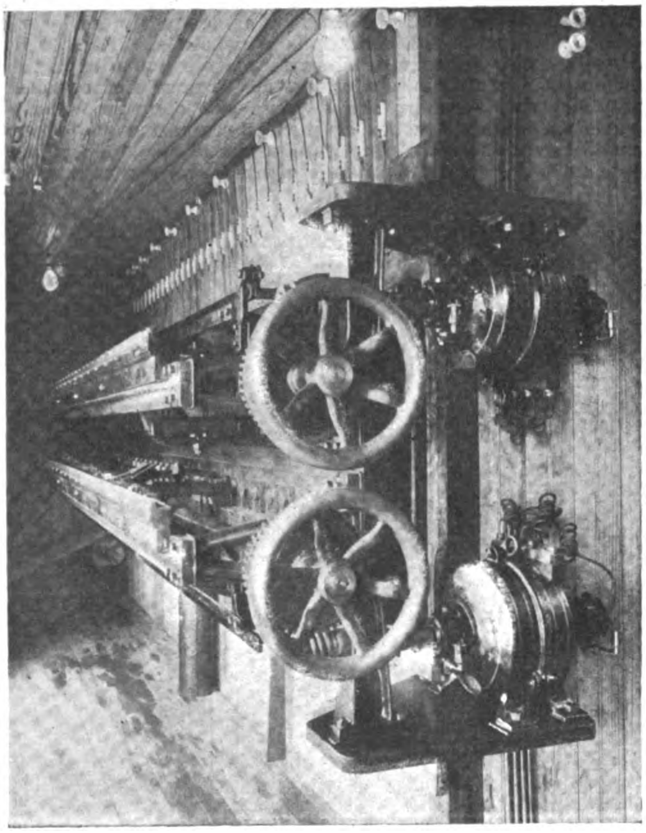

Fig. 60.—Cell Regulating Switches and Motor Driving Gear, Second District, Brooklyn Edison Station.

The second battery which this company is now having installed consists of 156 cells, having a total capacity of 1,200 amperes for ten hours, 3,000 amperes for three hours, or 6,000 amperes for one hour. This battery is located in the station known as the Citizens' Station, situated nearer their main generating station.

The Brooklyn Edison Company are now adopting the high tension system for generating and transmitting, the distribution being low tension direct current over their Edison three-wire system by means of rotary transformers and storage batteries. This will mean that the bulk of the current is generated at a large station on the water front, from which it is transmitted at high pressure to sub-stations scattered all over their district, where it is distributed as direct current through the rotary transformers and batteries. The above mentioned battery plants are the first two sub-stations of this description and will be supplemented by others as the system is developed.

WEISBACH AND RANKINE AS AUTHORITIES ON HYDRAULICS.

BY W. E. WINES.

In your issue of May 26 there appeared a letter from Mr. F. M. F. Cazin, criticising a statement made by me in regard to Weisbach and Rankine. In reply I beg to call attention to the fact that I did not state that these authorities always took the position mentioned. Both Weisbach and Rankine demonstrate that when a jet of water strikes a vein or surface it imparts all its energy to that surface when the velocity of the vane is one-half that of the jet and the motion of the jet is completely reversed.

But in discussing the theory of turbines they insist upon a different principle, viz., that the tangential component of the velocity of the entering water should equal that of the buckets. For example, Rankine (Manual of the Steam Engine, p. 178) says: "In order that the water may work to the best advantage, it should enter the wheel without shock and leave it without whirling motion; for which purpose, the velocity of whirl on first entering the wheel should be equal to that of the first circumference of the wheel, and the velocity of whirl relatively to the wheel, on leaving the wheel, should be equal and contrary to that of the second circumference of the wheel."

James B. Francis (Lowell Hydraulic Experiments, p. 94) says: "The proper velocity to be given to the wheel is an important consideration. Experiment 30, on the Tremont turbine, gives the maximum coefficient of effect for that wheel; in that experiment the velocity of the internal circumference of the wheel is .62645 of the velocity due to the fall acting on the wheel. . . . By this table it would appear that, as turbines are generally used, a velocity of 56 per cent. of that due to the fall acting upon the wheel would be suitable." Fifty-six per cent. is not very far from .5, which is the theoretical velocity of maximum efficiency, provided friction is neglected.

On page 52 of the Lowell Hydraulic Experiments, Francis says: "The turbine has been an object of deep interest to many learned mathematicians, but, up to this time, the results of their investigations, so far as they have been published, have afforded but little aid to hydraulic engineers." Prof. H. P. Trowbridge (Turbine Wheels, p. 6) says: "In other words, while the turbine wheel has been improved and its efficiency greatly increased, we look in vain for suggestions which might lead to such improvements, in the treatises on turbines, by Rankine, Weisbach, Bresse and others, which have been and are still most frequently studied for information on the subject."

HIGHEST BUILDING IN THE WORLD.

Architect George Sage is preparing plans for a fifty-nine-story office and studio building to be erected in the central part of New York City. The estimated cost of the building will be from $12,000,000 to $15,000,000, which will be furnished by a syndicate of Englishmen, who want to own the highest building in the world. The building will be 300 feet square. There will be five electric elevators, which will run upward through the center of the building at the speed of express trains. Water for the upper floors will be forced up by means of electric pumps in the basement. The building will have its own electric fire department.

HEATING WITH EXHAUST STEAM FROM CENTRAL STATIONS.

The Edison Electric Illuminating Company, of Topeka, Kan., has contracted with the American District Steam Company, of Lockport, N. Y., for nearly a mile of underground street mains for the purpose of utilizing their exhaust steam for the heating of buildings. The work will be commenced at once. The Illuminating Company will have an income the first year from heating of about $6,500, derived mostly from the sale of exhaust steam.

The Taylorville, Ill., Electric Company is also putting in an exhaust heating plant to heat the principal buildings of that town.

MR. H. A. WYCKOFF, of the Walton Electric Light Company, writes us from Delhi, N. Y.: "I am a regular subscriber for The Electrical Engineer and am much interested in the articles published and subjects treated upon. The last few copies have particularly interested me."

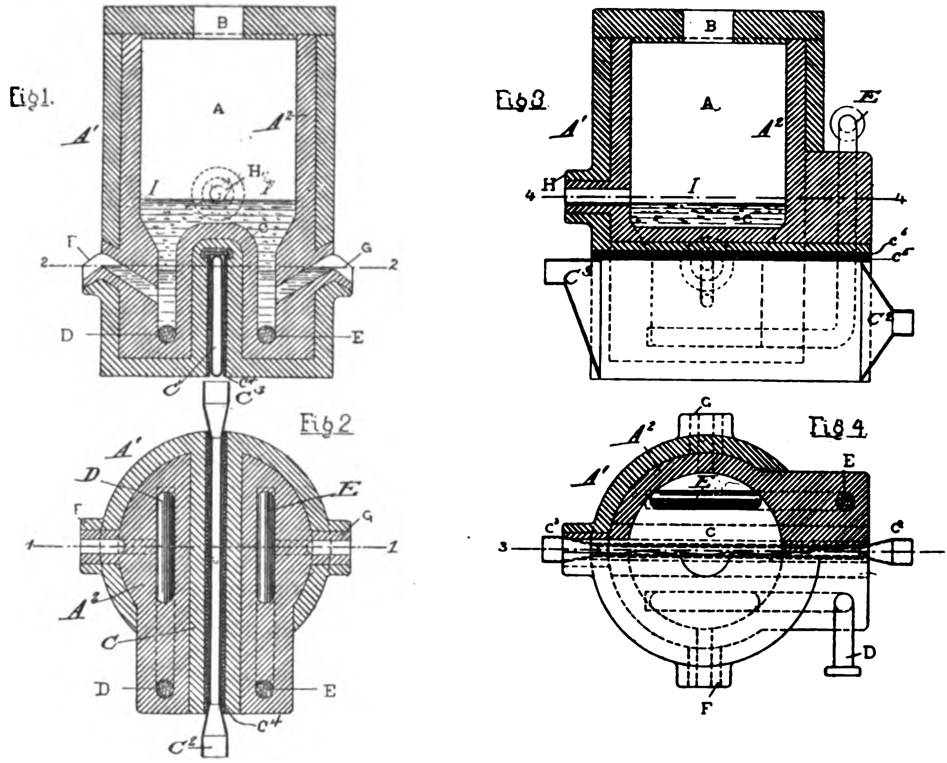
DE LAVAL'S METHOD OF ELECTRIC IRON SMELTING.

FOR some time past it has been understood that Mr. De Laval, the inventor of the steam turbine bearing his name, had invented a method of reducing iron to a state of great purity by means of the electric current, and that a number of large water-powers in Sweden were to be developed to carry out the process.

In a patent just issued in the United States to Mr. De Laval we find a description of a method for smelting iron which will prove of interest to our readers.

The accompanying engravings show in Fig. 1 a vertical sectional view on line 1 1. In Fig. 2 is shown a horizontal sectional view on line 2 2, Fig. 1. Fig. 3 is a vertical sectional view on line 3 3, Fig. 4; and Fig. 4 is a horizontal sectional view on line 4 4, Fig. 3, one-half, however, being in plan.

A indicates the furnace, into which, when iron is to be melted, spongy iron is introduced through the charging hole, B. A' is a casing of iron provided with a lining, A, of refractory material. In the lower part of the furnace there is located a bridge, C, of refractory material, extending transversely across the furnace, on each side of which bridge cavities are provided adapted to receive the pole-pieces, D and E, which are connected with the current generator. These pole-pieces consist of iron bars, which are inserted at the bottom of the furnace into the cavities between the bridge, C, and the wall of the furnace, as shown in the engravings.



FIGS. 1, 2, 3 AND 4.—DELAVAL ELECTRIC IRON SMELTING PROCESS.

F and G are two outlets for the metal, which are disposed as overflows, so that the metal flows out when it has risen to a certain height. The bridge, C, is represented hollow and a flattened pipe, C', passes through this hollow bridge in order to effect the requisite refrigeration of the bridge by conducting water or the like through the mouthpiece, C^2. C^3 is the outlet for the water or the refrigerating liquid.

When the furnace is to be put in action, the metal to be smelted is added through the hole, B, and the pole-pieces, D E, are connected with the generator of electricity. The metal thereby melts and runs away through the outlets, F G. If desired, an electrolyte may be introduced in the furnace for obtaining the necessary heat. In this case molten electrolyte, I, is poured in through the holes, B, and the pole-pieces, D E, are connected with the generator of electricity. The current then passes through the electrolyte and over the bridge, C, thus heating the electrolyte still more. The metal being now added sinks down through the electrolyte while being heated by the latter to the temperature of melting, and gathers, when fused, on the bottom of the furnace. The pole-pieces, D and E, melt also a little, so that the poles will consist of molten metal. As the metal is constantly supplied, sinks down through the layer, I, and gathers on the bottom of the furnace, this molten layer ascends at last, so that metal flows out through the outlets, F and G. Their height above the bottom of the furnace determines thus the distance between the two poles, or the so-called "pole-level," and consequently the way which the current must pass through the electrolyte from one pole to the other. In the same way the height of the electrolyte layer, I, is automatically regulated by the hole, H. The above method and furnace can also be employed to overheat a metal. The metal is in this case introduced in a fused state, and it obtains the overheat when passing through the electrolyte layer, which communicates its heat to the molten metal.

The electrolyte, above mentioned, does not act as a reducing material in the process, but only as a liquid-heating material, acting as a conductor merely. It follows, therefore, that alternating currents can be used as well as continuous. As an electrolyte, magnetic iron ore may be used for smelting iron.

ILLUMINATING THE NIAGARA CATARACT BY ACETYLENE.

There is a possibility that the first large public demonstration of the illuminating powers of acetylene gas will be made at Niagara Falls, where it is proposed to erect a dozen or more searchlights on Goat and Luna islands for the purposes of illuminating the grand cataract at night. The Acetylene Light, Heat and Power Company have offered to make this display of the powers of their gas through their manager, Mr. Joseph Devine. Some years ago electric searchlights were turned on the Falls with good effect, and since then it has frequently been proposed to re-establish them, they having proved a drawing card for summer evenings at this popular resort, where there is little amusement during the evening. The demonstration is expected to attract the attention of the delegates to the American Street Railway Association's convention next October, as acetylene is winning favor in some sections as a street car illuminant.

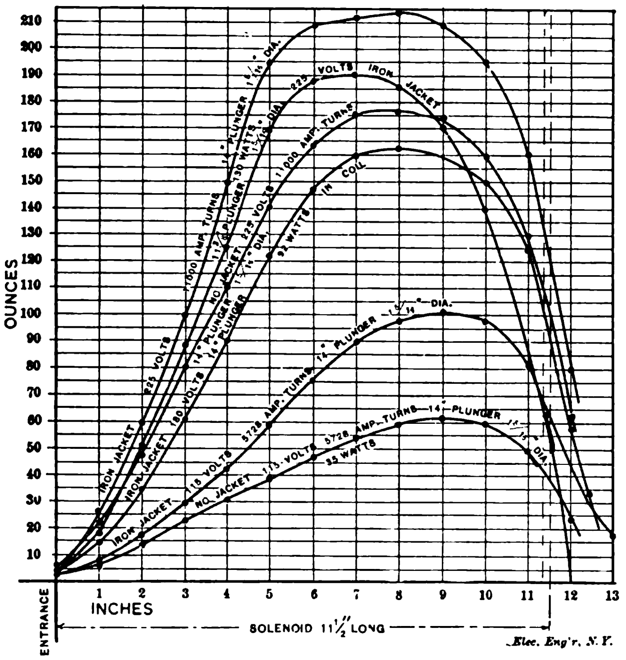
HOW PINTSCH GAS IS MADE.

The material used for the manufacture of Pintsch gas is crude or refined petroleum. In the plant constructed for the supply of Baltimore & Ohio cars in Pittsburg (which is a model plant), the furnace room contains four furnaces, each having an upper and a lower retort, in which the oil is thoroughly converted into a rich, permanent gas of the highest illuminating power known in the art. From the retorts the gas passes through ingeniously arranged apparatus in the purifying room, where it is thoroughly freed from all impurities; but for the purpose of car illumination it must be compressed in order to carry a sufficient supply in the small space available on passenger cars. The gas is then conducted from the purifying to the compressing room, in which are located two powerful compressors of special design, which compress the gas into storage cylinders used for this purpose. From these holders the gas is piped to the Baltimore & Ohio depot where it is supplied to the cars as required.

ACTION OF SOLENOIDS ON CORES.

BY W. H. CHAPMAN.

THE proper proportioning of the solenoids used in the Chapman voltage regulators manufactured by the Belknap Motor Company has necessitated a set of careful experiments, the results of which have been plotted in curves for convenient reference. Some of these curves are of considerable general interest as they show at a glance the effects of a magnetic return circuit, or, in other words, of an iron jacket and also the laws of increase of the force with the increase of the ampere turns.



CURVES SHOWING ACTION OF SOLENOID ON VARIOUS CORES.

The accompanying curves were taken from a simple solenoid 11½ inches long. The ordinates represent the ounces of force exerted on the plunger, and the abscissæ represent the distance that the end of the plunger has entered the coil at each observation. The various conditions under which the different curves were taken are designated on the curves themselves. Two different plungers were used as indicated; one of them was 14 inches long by 1 5-16 inches diameter, and the other one was 11⅜ inches long by 1 5-16 inches diameter.

LITERATURE

THE INDUCTION COIL IN PRACTICAL WORK. By Lewis Wright. New York and London. The Macmillan Co. 1897. Cloth 12mo. Illus. 172 pp. Price, $1.25.

This is a simple and admirable book of the new class called into being by the development of Röntgen ray work. The opening part is devoted to an exposition of principles and practice in connection with induction coils. The next part deals with experiments in vacua; there is a good chapter on spectrum work; and then comes an excellent section in regard to the Röntgen ray and various types of vacuum tubes designed specially for that line of investigation. Why such a serious and well intentioned volume should issue without an index is more than we can venture to explain.

LETTERS TO THE EDITOR

THE ENCLOSED ARC LAMP.

IN the paper on "Recent Progress in Arc Lighting," read by Prof. Elihu Thomson at the Niagara Falls Convention of the National Electric Light Association, and which is now being published seriatim in The Electrical Engineer, much space is naturally devoted to the discussion of the enclosed arc lamp. Prof. Thomson remarks that "the enclosed arc lamp, broadly speaking, is an outcome of the ability to secure very nearly pure carbons." He also claims to have made some experiments in this field in 1879 and states that, "for many years after that date (1879) there were not to be found such pure carbons as would give so little deposition as is required to work an enclosed arc practically."

I am much surprised that one so well posted in the state of the art as Prof. Thomson, should ascribe the success of the enclosed arc to the "ability to secure very nearly pure carbons." As pointed out in my recent paper, read before the International Society of Electricians, at Paris, in January of this year, the history of the development of the enclosed arc is the record of a succession of failures up to 1894, when, as a result of my work the first successful enclosed arc lamps were put on the market. The commercial enclosed arc lamp is only three years old. Of the thirty odd thousand enclosed arcs now in successful daily operation in this country, nine-tenths have been installed within the past two years. Was this phenomenal growth due to the discovery of a pure carbon? Inasmuch as practically the same grade of enclosed arc carbon as is now extensively used was to be found in the open market at least five years before the advent of the successful enclosed arc lamp, the sudden rise must have been due to another cause.

As Prof. Thomson has remarked, and as pointed out by me in my Paris paper, "the idea of burning an arc in a practically closed and relatively small glass chamber is quite old." But the idea of operating a high potential arc within an enclosure and maintaining the arc with a small expenditure of current is, however, new. Although years before, I had used very nearly pure carbons in my investigations with enclosed arcs, still the experiments resulted in failure after failure until the idea of the high potential arc was evolved by me. This method of operation, an account of which was first given to the National Electric Light Association at the Washington, D. C., Convention in February, 1894, involves an essential principle of all practical enclosed arcs, and marked the beginning of the commercial enclosed arc lamp industry.

As a contribution to the history of the art, Prof. Thomson's reference to his unsuccessful experiments in this line is interesting, as is all that comes from his pen; but it is quite clear that the successful introduction of the enclosed arc system was not due to his efforts. L. B. MARKS.

New York, June 14, 1897.

MR. NICHOLLS' ACKNOWLEDGMENTS TO THE ELECTRICAL PRESS.

My term of office as president of the National Electric Light Association expiring on the 1st proximo, I desire, as one of the last acts of my administration, to thank yourself and the editors of other electrical journals, officially and personally, for the interest you have shown in the work of the association during the past year and for your kindness in promptly publishing any information that has been forwarded to you for that purpose by the association.

As I took occasion to point out in my annual address, the electrical industry at large owes a debt of gratitude to the electrical press, and, for my part, I am glad to have had an opportunity of acknowledging this obligation.

FREDERIC NICHOLLS.

MR. E. E. GAGE, superintendent of the St. Johnsbury, Vt., Electric Company, writes: "We like The Electrical Engineer very much. It is well worth the price."

MR. C. J. STEBBINS, of Kasota, Minn., says, under date of June 23: "I have been a continuous subscriber to The Electrical Engineer for six years and still consider it the most reliable electrical paper published."

LEGAL NOTES

LITIGATION ON PAPER TELEPHONE CABLES.

The National Conduit Cable Company, of New York City, has begun an action against the New York and New Jersey Telephone Company, which will be tried in the United States Circuit Court in Brooklyn in August. The plaintiff alleges that the defendant has infringed on its patents. The National Company a year ago purchased the Norwich Insulated Wire Company and secured title to certain letters patent in the United States and the rights to certain improvements in electric conductors, consisting of covering wires with spirally wound strips of paper composed of purely vegetable fiber. This type of cable has come very largely into use for telephone cable work.

THE NEWARK TELEPHONE COMPANY DENIES INSOLVENCY AND MAKES CHARGES.

The Newark Telephone Company has filed in the New Jersey Court of Chancery its answer to the application of Frank H. Hall, a dissatisfied stockholder, for the appointment of a receiver. The answer denies the charge of insolvency and says that while the company has debts to the extent of $36,000, only a trifling amount of this is due. The answer also says that the company is doing a prosperous business.

It is admitted that Hall was denied the privilege of examining the books, but it is charged that the officers only refused the permission when they became satisfied that he was in the employ of the New York and New Jersey Telephone Company, a rival organization using the Bell system.

The answer admits having issued 20,000 shares of stock to the Best Telephone Company in return for patent rights, but claims that this was not more than the value of the right thus obtained.

THE STERNE TELEPHONE SUBSCRIBER FIGHT IN NEW YORK.

The Appellate Division of the New York Supreme Court has handed down the following decision: In the action of Simon Sterne against the Metropolitan Telephone and Telegraph Company, of New York City, to enjoin the latter from increasing the amount of the annual rental for the use of the telephone in his office from $150 to $240, the Appellate Division restored an order, which had been vacated by the court below, to examine the defendants for the purpose of showing that the telephone business under the new tariff would yield exorbitant profits. The court holds that on issues as passed by the pleadings, the facts as to profits and cost of operation have an important bearing, and that the plaintiff was not obliged to wait until the trial to examine the defendant officers, for they are non-residents and possibly could not be subpoenaed for the trial.

SOCIETY & CLUB NOTES

NORTHWESTERN ELECTRICAL ASSOCIATION.

The fifth semi-annual convention of the Northwestern Electrical Association will be held at La Crosse, Wis., commencing on Wednesday morning, July 21 next. All interested in electrical matters, whether members of the association or not, are cordially invited to attend this meeting. Cameron Hotel, $2.50 per day, will be official headquarters, and Hotel Law, $2.00, and Hotel Bronson, $1.00, will also accommodate delegates. 110 volt direct, and 7,200 volt alternating current, with abundant space, will be at the service of exhibitors. Address F. A. Copeland, La Crosse, Wis., for hotel and exhibit accommodations. The Western Passenger Association has granted a 1⅓ rate, conditional, however, upon 100 certificates of attendance. Special sleepers via C. & N.-W. Ry. will leave Chicago at 10:15, and Milwaukee at 8 o'clock, on Tuesday evening, July 20, running together from Madison via Elroy. Delegates from or through Chicago should apply for reservations to George Cutter, 1104 Rookery Building, Chicago. Those from or through Milwaukee, to Mr. Mercein. Papers on "Meter Tests," "220 Volt Lamps," "Use of Oil in Transformers," "Utilization of Exhaust Steam," "Evolution of the Incandescent Arc Lamp," "Rotary Transformers" and "Fuels for Central Stations" will be presented by Prof. D. C. Jackson of Wisconsin University, Prof. G. D. Shepardson, of Minnesota University, Prof. R. B. Owens, of Nebraska University, George L. Thayer, of Iowa, O. M. Rau, of Wisconsin, C. F. Scott, of Pittsburg, and John C. McMynn, of Illinois. The Entertainment Committee has arranged an enjoyable programme, including a river excursion and picnic lunch, trolley parties, etc. Mr. T. R. Mercein, of Milwaukee is secretary.

TRAIN DISPATCHERS IN CONVENTION AT DETROIT.

An important meeting of the Train Dispatchers' Association of America was held at the Hotel Cadillac, Detroit, during last week. The attendance was excellent and much interest was shown in the work of the convention. Montreal was chosen as the next place of meeting.

Unless all signs fail, the convention will mark an era in the life of the organization looking toward greatly increased prosperity in the future. Six years ago at the convention in New Orleans nearly one-half of the members withdrew from the association because of a difference of opinion that existed concerning the advisability of incorporating in the constitution certain clauses giving the organization the standing of a labor union in the adjustment of difficulties that it was thought might arise between the several roads and the dispatchers. The plan was defeated, but the feeling was so strong for and against it that harmony seemed for the time impossible.

At that time the association was freighted with a contract with the publishers of a railway publication to contribute a certain considerable sum each year toward the support of that publication. While the membership of the association was large, there was no difficulty in complying with the terms of the contract, but when so many withdrew, financial troubles grew apace. As a result of these conditions, the association has been laboring under a debt amounting to about $2,000 at the present time. It is expected, however, that during the coming year, the whole amount will be wiped out and that the next convention will find the association free from debt of any sort. Action looking to this end was taken at Detroit, when members were urged to subscribe something toward raising the amount. There is a considerable amount due the association from members who are in arrears for dues, and an effort will be made to collect it. In addition it is expected that the membership will be largely increased during the year, and individual members will contribute in various ways toward the effort.

PERSONAL

DYER & DRISCOLL.

MESSRS. DYER & DRISCOLL, we learn, have removed to the new Bank of Commerce Building, 31 Nassau street, New York City, from their long-established offices on Wall street, some time before the 1st of May last. The announcement of removal was delayed until the firm had become quite settled and ready to handle the business of new clients that might be brought to them.

High class patent soliciting is still a specialty of the firm, and particularly in connection with electrical subjects. The success of this firm in litigations arising out of patents relating to electrical inventions is too well known to require comment. The litigation on the Edison patent on the incandescent lamp is one among many which the firm actively brought to a successful termination, and that it has continued for so many years to act as Mr. Edison's patent solicitors speaks volumes as to the high class of work done by it.

MR. H. B. COX has been visiting, before his return to England, the city of Cincinnati, where he did so much of his earlier electrical work. He was born at Zanesville, Ohio, the home also of his cousin the late distinguished statesman, Hon. S. S. Cox, of whom the letter carriers of this country lately put up a statue. Mr. Cox began active life in Cincinnati in the Western Union service.

MR. PERRY S. HEATH, first assistant postmaster general, has been appointed by the United States Court of Claims sole referee in the dispute between the Government and the Western Union Company as to tolls for government messages under Mr. Wanamaker's administration of the post office.

REPORTS OF COMPANIES

ANNUAL MEETING OF THE WESTINGHOUSE ELEC. & MFG. CO.

THE Westinghouse Electric and Manufacturing Company on Tuesday, June 22, 1897, declared a quarterly dividend on its preferred stock of 1¾ per cent.

On Wednesday, the annual meeting of the stockholders took place at the factory of the company in East Pittsburg, Pa. The annual report of the company was read, showing the condition of the company to be a prosperous one. The same Board of Directors of last year were re-elected, they composed of August Belmont, Lemuel Bannister, Geo. Hebard, Henry B. Hyde, Marcellus Hartley, A. M. Byers, N. W. Bumstead, Chas. Francis Adams, Brayton Ives and Geo. Westinghouse, Jr.

The report for the year ending March 31 last showed assets, $17,965,295, of which $1,647,754 was bills and accounts receivable, $1,636,612 material on hand, and $4,689,081 charters, franchises and patents. The bills and accounts payable amounted to $691,685. The report says that a reduction in the surplus account of $1,577,735.93 is due to writing off bad debts, disbandment of old factories, obsolete machinery, etc. On June 4, an increase in the capital stock from $10,000,000 to $15,000,000 was authorized and $3,000,000 of the new stock was sold to the Security Investment Company, of Pittsburg, for $2,489,000, of which $1,260,000 was in cash and the remainder in property and secured notes; $347,419 was expended during the year for the purchase of new patents and plants.

At the stockholders meeting it was announced that the St. Lawrence Construction Company, of New York, had awarded to the company a contract for fifteen 5,000 horse-power generators, which are to be erected at their plant at Massena, northern New York. This is the largest single order ever given for electrical apparatus, and the amount directly involved is about three-quarters of a million dollars.

This contract together with that recently given by the Cataract Construction Company, of New York, for five 5,000 horse-power generators for installation at Niagara Falls, New York, makes the total of twenty 5,000 horse-power generators, having a total capacity of 100,000 horse-power, which have been ordered from the Westinghouse Electric and Manufacturing Company this year.

The five generators for Niagara Falls are well under construction, and the other fifteen required by the St. Lawrence Company will be immediately proceeded with and their construction will give employment to a large number of men.

These orders cover only the apparatus for generating electricity, and there will necessarily be required other apparatus of equal capacity for the utilization of the electrical energy produced by these great generators, and the Westinghouse officials expect that a large proportion of the additional apparatus will be ordered from their company by reason of their having already secured the contract for the principal apparatus.

NORTH AMERICAN CO.

ON June 16 the annual meeting of the North American Company was held in Newark, N. J. The directors whose terms of office expired were re-elected. They are Messrs. H. C. Payne, John I. Beggs and Edward Edes. The annual report shows that the boycott of the Milwaukee Railway continued until about July 1, with a loss in gross earnings for May and June of about $125,000. The force was entirely changed and the lingering effects of the boycott increased expenses and diminished receipts for some months. The efforts of the city council to reduce fares is detailed; the matter is being fought in the courts, and should reach a decision during the coming winter. The company is confident of winning its case.

In February last the Pabst Light, Heat and Power plant and the Milwaukee & Wawatoso Electric Railway were acquired, so that all the electric street railways in the city and immediate suburbs are owned by the company. Gross earnings of the Milwaukee Company, January 1 to May 1, 1896, were $502,891, the largest in its history, and for the same four months this year they have been $503,487. The five months of this year they have been $632,231, against $563,766 last year, an increase of $68,464. Any improvement in general business will increase the company's earnings.

Cincinnati Edison earnings have increased. New machinery must be bought, and a new central station must be built upon a larger site. The present mortgages on the property will be retired, and a new first mortgage, large enough to provide the new capital, will be issued. Enough of these bonds have been sold to a syndicate this month to retire the bonds and pay for the new station.

The treasurer's report follows:

Assets May 31.	1897.	1896.	Decrease.
Mil. Ry. & Light pf.	$2,390,800	$2,390,800	
Mil. Ry. & Light com.	3,078,000	3,078,000	
Cin. Edison stock	382,733	382,733	
Milwaukee 5s.	100,000	......	*$100,000
Cin. Edison 5s.	105,000	......	*105,000
Miscellaneous securities	25,204	39,741	14,537
Accounts receivable	222,403	253,130	30,727

Interest and dividend rec. and account	39,256	129,806	95,550

---

* Increase.

INTERNATIONAL BELL TELEPHONE COMPANY TO QUIT.

Preparations are being made by the International Bell Telephone Company to discontinue business. The company once had a capital of $1,750,000, but it was reduced to $1,000,000. It has now been decided to reduce it to $750,000 by the payment to the stockholders of a cash dividend of $250,000. This concern introduced the telephone in several foreign countries, the principal one being Russia, where it has a twenty years' contract with the government. This contract expires in 1901, and it is thought that the Russian government will then avail itself of the contract right to take possession of the company's property. Meantime the company is selling its other business in Sweden, Holland, Switzerland and Belgium. The officers think they will be able to pay the stockholders in full out of the proceeds of these sales and the earnings in the next few years.

BELL TELEPHONE DIVIDEND.

The American Bell Telephone Company has declared the regular quarterly dividend of 3 per cent. and an extra dividend of 1½ per cent., both payable July 15th. It has been the custom of the company since and including 1895 to pay 15 per cent. in dividends per annum, the January and July periods carrying an extra payment of 1½ per cent. each. In 1894, 16½ per cent. was paid, in 1893 18 per cent., in 1892 15 per cent., and in the three years previous 18 per cent. per annum.

MR. R. C. FOSTER, of the Schneider Manufacturing Company, 1140 Hamilton street, Cleveland, O., reports a large demand for their water fan motors in the hundreds of towns where no day electrical circuits exist. As the warm weather advances, orders pour in by telegraph for prompt shipment by express. Electrical supply houses are ordering considerable quantities, and show great interest in the subject. A big demand is also springing up for South American trade.

THE BULLOCK ELECTRIC MANUFACTURING COMPANY, Cincinnati, O., report business as very good. They have just secured what is probably the largest order ever given for printing press equipment with electric motors, viz., the plant of the San Francisco "Examiner," one of Mr. Hearst's papers.

MR. F. M. HAWKINS, so long connected with the Electric Engineering and Supply Company, Syracuse, N. Y., and for the past three years their New York representative, has taken the agency for Pass & Seymour's well known electrical china specialties and the Crouse-Hinds Electric Company knife switches and switchboards. He has opened offices at No. 39 Cortlandt street, where he will carry and keep in stock a full line of the above firm's goods. He reports business good and improving.

INVENTORS RECORD

CLASSIFIED DIGEST OF U. S. ELECTRICAL PATENTS ISSUED JUNE 15, 1897.

Alarms and Signals:—

ELECTRICAL CIRCUIT-CLOSING THERMOMETER. A. Luraschi, London, Eng., 584,382. Filed March 15, 1897.

Means for insuring permanent electrical contact between the movable and fixed parts of the conductor within the bore of the tube; also relates to the mode of forming the movable terminal and insuring the fixity of its position after adjustment.

ELECTRICAL ADVERTISING ANNUNCIATOR FOR CARS. J. P. Orr and G. H. Fugh, Pittsburg, Pa., 584,700. Filed September 29, 1896.

Details of construction.

Batteries, Primary:—

PRIMARY CELL. I. Kitsee, Philadelphia, Pa., 584.474. Filed September 15, 1896.

A positive element consisting of a containing cup of a material designed to remain inert, a conducting rod passing through the cup and a solid body of an alloy of mercury and a metal, as zinc, cast so as to fill the space between cup and rod, the surface of said body only being exposed.

Batteries, Secondary:—

SECONDARY BATTERY PLATE AND METHOD OF PRODUCING SAME. W. P. Patton, Jersey City, N. J., 584,649. Filed February 15, 1897.

A secondary battery plate comprising a sheet metal partition coated with soluble inert material on each side, and having openings along the edges, and cast metal perforated sides which are integrally united through the openings in the partition.

Conductors, Conduits and Insulators:—

MECHANICAL CLIP. H. H. Luscomb, Hartford, Conn., 584,383. Filed November 18, 1896.

A clip specially designed for holding trolley wire of 8-section.

FLEXIBLE CONDUIT. A. L. Tucker, Chicago, Ill., 584,428. Filed October 23, 1896.

The combination with a lining composed of annular sections of a spiral winding of tape inclosing said annular sections.

INSULATOR. S. H. Libby, Schenectady, N. Y., 584,476. Filed February 10, 1897.

Claim 1. In a conductor rail insulator, the combination of a metal base, a body of insulating material mounted upon the base, a rail clamp secured to the conductor rail and prevented from moving independently of the insulator by frictional engagement therewith.

INSULATOR. S. H. Libby, Schenectady, N. Y., 584,477. Filed February 10, 1897.

The combination of a conductor rail, a body of insulating material situated each side of and supporting the rail, and a support for each body of insulating material permitting a limited amount of vertical movement of the conductor rail.

Distribution:—

SYSTEM OF DISTRIBUTION. E. W. Rice, Jr., Schenectady, N. Y., 584,482. Filed February 7, 1896.

The method of maintaining potential upon a two-wire system of distribution connected with a three-wire system, which consists in supplying the two-wire system with energy from both sides of the three-wire system.

Dynamos and Motors:—

APPARATUS FOR CONTROLLING ELECTRIC MOTORS. B. A. Fiske, United States Navy, 584,341. Filed March 6, 1896.

Controls the speed and direction of the motor by varying the e. m. f. of the generator.

ARMATURE FOR DYNAMO ELECTRIC MACHINES. H. H. Wait, Chicago, Ill., 584,431. Filed February 27, 1896.

Openings are provided through the armature core for the passage of air to ventilate the armature.

REGULATING SPEED OF INDUCTION MOTORS. E. Danielson, Stockholm, Sweden, 584,577. Filed May 2, 1896.

A number of induction motors mechanically connected together, the motors having different numbers of poles, and means of operating them singly or in tandem groups.

Lamps and Appurtenances:—

LAMP SOCKET. E. M. Bradford, Boston, Mass., 584,321. Filed November 19, 1896.

A device whereby the current is automatically closed upon the withdrawal of the lamp from the socket or may be closed without such withdrawal.

ELECTRIC ARC LAMP. I. H. Hegner, Paris, France, 584,356. Filed February 4, 1896.

Has for its object to group together two or more arc lamps in series or parallel and to regulate the feed according to the total resistance of the group as well as to the resistance of each individual lamp.

INCREASING ILLUMINATING POWER OF ELECTRIC ARC LAMPS. P. Mersch, Paris, France, 584,694. Filed April 14, 1897.

Composition for increasing the illuminating power of electric arc lights, consisting of the admixture of carbonate of magnesia, asbestos, or some other incombustible textile product, and silicate of potash.

INCANDESCENT ELECTRIC LAMP.—C. E. Scribner, Chicago, Ill., 584,750. Filed April 24, 1893.

Object is to enable a two-part lamp to be so constructed that the two parts may be taken apart when desired and either or both used again.

Miscellaneous:—

PRODUCTION OF ELECTRIC SPARKS FOR SIGNALS OR THEATRICAL EFFECTS. V. Tabulewitsch, St. Petersburg, Russia, 584,427. Filed Jan. 16, 1897.

The essential part of the lamp is the burner or the apparatus for obtaining an uninterrupted series of sparks between the carbon and the steel electrode employed.

Railways and Appliances:—

ELECTRIC RAILWAY. T. W. Kloman, Montclair, N. J., 584,511. Filed April 30, 1896.

Relates to a switch mechanically actuated by the passage of the car.

TROLLEY STAND. S. H. Short, Cleveland, Ohio, 584,607. Filed February 16, 1897.

Object is to prevent lateral movement of the trolley arm when in service, but which will permit the trolley arm to be reversed in position relative to the car when desired.

TROLLEY STAND. S. H. Short, Cleveland, Ohio, 584,606. Filed February 16, 1897.

Similar to above.

ELECTRIC RAILWAY. H. M. Jones, Meriden, Conn., 584,639. Filed August 12, 1896.

A conductor having a longitudinal slot at its top, and a tubular cable for normally closing said slot, the cable consisting of a spiral coil, the spirals being arranged close together, yet adapted to open or stretch at points lifted from the slot.

BOND FOR ELECTRIC RAILWAYS. F. T. Newbery, San Francisco, Cal., 584,644. Filed Aug. 25, 1894.

The contiguous ends of the rails are drilled with corresponding holes into which a dowel pin is pressed.

Switches, Cut-Outs, Etc.

LIGHTNING ARRESTER AND MULTIPLE AUTOMATIC FUSE-BLOCK. G. X. Gast, New Orleans, La., 584,632. Filed April 10, 1897.

Details of construction.

Telegraphs:—

ELECTRIC CIRCUIT PROTECTOR. A. L. Creelman, Memphis, Tenn., 584,462. Filed August 11, 1892.

Consists in combining with the usual instruments in a Morse circuit an apparatus controlled by a magnet and train of gear for making and breaking both the ground-circuit and a shunt-circuit around all the instruments in the station and also operating to give an alarm on a bell, and in controlling the operation of resetting such apparatus.

ELECTRIC SIGNAL. A. L. Creelman, Chicago, Ill., 584,463. Filed August 17, 1895.

An alarm or signal designed to be operated electrically by the closure of a main circuit and to continue its operation after the circuit is opened again.

CIRCUIT PROTECTING SOUNDER. A. L. Creelman, Chicago, Ill., 584,465. Filed May 18, 1896.

Operates to automatically give an alarm and shunt the instruments when the main line current is interrupted for a predetermined time and to open a ground circuit.

TELEGRAPH SOUNDER. A. L. Creelman, Chicago, Ill., 584,464. Filed September 3, 1895.

Relates to that class of sounders commonly known as "receiving-sounders," and used in connection with circuit protecting devices.

TELEGRAPHIC SOUNDER. A. L. Creelman, Chicago, Ill., 584,466. Filed July 3, 1896.

Comprehends a sounder provided with a second and third electromagnet and with devices controlled thereby for making and breaking connections through which various operations are effected.

PERFORATOR FOR ELECTRIC TELEGRAPHS. C. G. Burke, Brooklyn, N. Y., 584,722. Filed September 4, 1896.

Details of construction.

Telephones:—

MAGNETO APPARATUS. H. H. Eldred, Brooklyn, N. Y., 584,338. Filed April 4, 1896.

A magneto instrument which is both a magneto-generator and a magneto bell.

PARTY LINE TELEPHONE SYSTEM. W. H. Harter, Norwalk, Ohio, 584,352. Filed August 10, 1896.

A harmonic selective signal system.

AUTOMATIC ELECTRIC SIGNAL TRANSMITTER. A. B. Macklin, New York, 584,384. Filed August 7, 1896.

Details relating to a signaling instrument for automatic telephone exchanges.

TELEPHONE SYSTEM. F. R. McBerty, Downer's Grove, Ill., 584,393. Filed May 14, 1896.

Applies to systems of current supply for telephone transmitters comprising single wire circuits provided with a common return. Its object is to reduce or eliminate the resistance of the common return wire, and thus to avoid cross-talk, which would result from resistance in the return wire.

TELEPHONE LINE CIRCUIT. C. E. Scribner, Chicago, Ill., 584,415. Filed August 1, 1895.

Concerns the sub-station apparatus of metallic circuit telephone lines, its purpose being to so arrange the telephonic and signaling appliances at the sub-station as to dispose with all switches.

APPARATUS FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 54,414. Filed April 26, 1893.

Object is to provide a mechanically actuated device controlled by means of electromagnets for exhibiting or withdrawing the indicator of the annunciator.

ELECTROMAGNET. C. E. Scribner, Chicago Ill., 584,416. Filed November 4, 1895.

The object of the invention is to provide a polarized signal bell for telephone lines which shall remain undisturbed by current continuously flowing through it, but shall be sensitive to alternating signaling currents.

TELEPHONE CIRCUITS. C. E. Scribner, Chicago, Ill., 584,417. Filed November 4, 1895.

Designed to permit a different mode of operating the telephones in event of the complete discharge of the local storage battery to avoid interruption of service.

SPRING JACK FOR TELEPHONE SWITCHBOARDS. C. E. Scribner, Chicago, Ill., 584,418. Filed July 20, 1896.

Details of construction.

TELEPHONE TRANSMITTER. H. C. Alexander, Bonham, Tex., 584,618. Filed February 27, 1897.

Details of construction. Of the Hunnings type.

TELEPHONE. C. C. Gould, Philadelphia, Pa., 584,787. Filed February 9, 1897.

Uses a plurality of transmitters, batteries and coils.

TRADE NOTES & NOVELTIES

THE NUNGESSER DRY BATTERIES.

THE accompanying engravings illustrate two types of dry batteries made by the Nungesser Electric Battery Company, of Cleveland, O. The square form shown, when properly used in call bell work, it is claimed, will give from 5 to 8 years' service without any attention whatever, and enjoys corresponding long life on other open circuit work.

THE NUNGESSER DRY BATTERY.
FOR OPEN CIRCUIT SERVICE.
NUNGESSER ELECTRIC BATTERY CO.
CLEVELAND
THE 1900 DRY BATTERY
FOR OPEN CIRCUIT SERVICE ONLY
MANUFACTURED BY NUNGESSER ELECTRIC BATTERY CO.
CLEVELAND, OHIO.

FIGS. 1 AND 2.—THE NUNGESSER DRY BATTERIES.

The Nungesser Company also manufacture batteries for closed circuit work. The cells have an e. m. f. of 1.45 volts and very low internal resistance. They are made in three sizes, having, respectively, 300, 600 and 1,200 ampere hours capacity. The former size is specially adapted for telephone and telegraph, gas lighting and signal work; while the latter sizes can be used for driving fans, sewing machines, motors, electric pumps, jewelers' and dental lathes, phonographs and other light work.

When these cells are not at work, no local action takes place and no material is consumed.

For testing purposes and as igniters of portable gas and gasoline engines the company make several sizes of chloride of silver batteries, with hard rubber cells. These have an e. m. f. of 1.10 volts.

THE NEW SIEMENS-HALSKE COMBINATION.

With regard to the statement in The Electrical Engineer last week about the consolidation of the Siemens-Halske Electric Company with the Pennsylvania Iron Works, of Philadelphia, it is stated that a majority of the stock of the Chicago company has already been exchanged for the stock of the Pennsylvania. The minority stockholders have sixty days in which to accept the offer of the Eastern concern. With a combined capital of $3,250,000, the two companies will manufacture street railway machinery for the four big cities.

At the annual meeting of the Chicago concern the directors elected were as follows: Charles T. Yerkes, of Chicago; W. L. Elkins, Jr., of Philadelphia; R. Suydam Grant, of New York; Charles E. Yerkes, of Chicago; B. W. Grist, of Philadelphia; F. W. Whitridge, of New York; W. T. Butler, of New York; E. T. Rice, Jr., of New York, and Martin Maloney, of Philadelphia. The new directors are C. T. Yerkes, W. L. Elkins, Jr., and B. W. Grist. Elkins is the son of W. L. Elkins, Sr., of Philadelphia. The directors then elected officers headed by Charles E. Yerkes, son of Charles T. Yerkes, of Chicago.

Whether the name of the Chicago concern will be dropped or changed has not yet been decided.

The capital stock of the Pennsylvania company consists of $1,750,000 six per cent. non-cumulative preferred and $1,500,000 of common stock. The Siemens-Halske capital is divided into $700,000 of preferred and $1,275,000 of common. The Philadelphia company offered $1,000,000 of its preferred in exchange for the $700,000 of Siemens-Halske preferred on a basis of something over one share of the Pennsylvania's stock for one of the Chicago company's.

FAN DAYS.

Notwithstanding the unusually cold weather experienced all over the country during the month of May, the Electric Appliance Company report that the few days of hot weather in June started the fan business going in good shape, and give promise of a prosperous fan season. The Electric Appliance Company state that they still have some copies of their fan motor catalogue left, which they will be glad to send to the trade upon application. It is a complete book of all styles of fan motors.

ASSIGNMENT OF THE ELEC. ENGINEERING AND SUPPLY CO. OF SYRACUSE, N. Y.

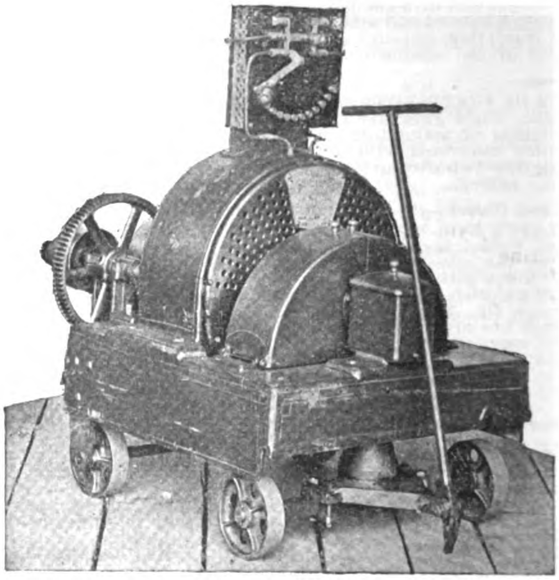
The Electrical Engineering and Supply Company, whose stores and offices are located at Nos. 308 and 310 West Jefferson street, Syracuse, N. Y., has made a general assignment for the benefit of creditors. Benjamin Stolz is named as assignee, and is given an irrevocable power of attorney to close up the affairs of the concern. There are no preferred creditors, all claims to have an equal opportunity in the settlement.

The company was organized in December, 1889, with capital stock of $25,000. Three years later the capital was doubled. According to the last report, the assets of the concern amounted to $92,000, with liabilities not to exceed $36,800. The officers of the company were: H. C. Hodgkins, president; J. L. Hines, vice-president; H. G. Gorke, treasurer and manager; H. A. May, secretary. The cause of the failure is given as hard times and slow collections.

CARD PORTABLE MOTOR.

IN large machine shops, structural iron works and other places where drilling or light boring has to be done on heavy material, much time can be saved by the use of a motor suitably mounted for easy transfer from place to place. The frequent calls for such a tool have caused the Card Electric Company of Mansfield, Ohio, to bring out the mounted motor illustrated in the accompanying cut.

All the working parts of the motor are enclosed as a protection against accidents from dirt or careless handling of material about it. The cone pulley shaft is driven from the armature shaft by gearing and the ratio of the gears is such that the cone pulley is made to run as near 200 r. p. m. as possible. On the armature shaft is a small pulley which can be used for driving high speed machinery direct.



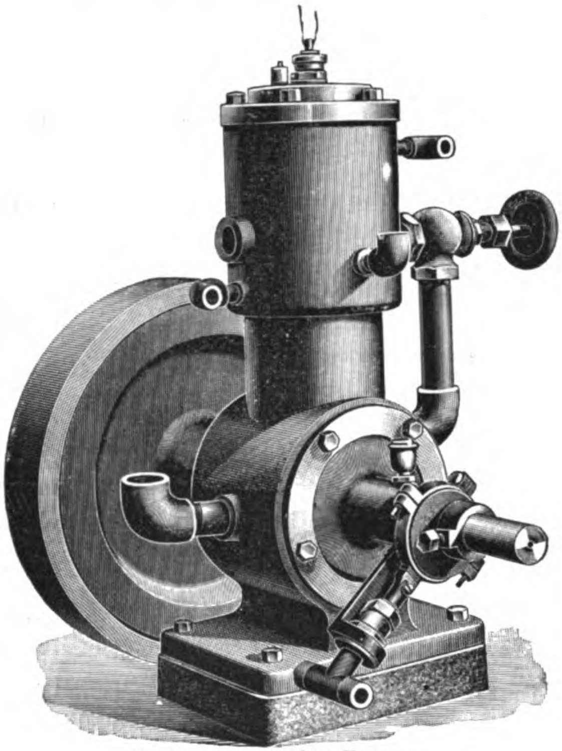
THE CARD PORTABLE MOTOR.

The starting rheostat is non-combustible and has a double pole switch mounted on it, and as all the connections to the motor are made before shipment from the factory, nothing has to be done to put the motor in operation but connect the line wires to it.

These mounted motors are manufactured by the Card Company in sizes from 2 to 12 horse-power inclusive, and purchasers are furnished a list of gears from which they can select a pair to give the cone pulley a speed suitable for their requirements.

THE PALMER ONE H. P. GAS OR GASOLENE ENGINE.

MANY amateurs have use for a small engine, and for such the Mianus Electric Co., of Mianus, Conn., have designed the 1 h. p. vertical gas or gasolene engine illustrated in the accompanying engraving. The company furnish either the complete engine or castings with working drawings, so that amateurs can, if they choose, finish and assemble the parts themselves. The engine is built on the two-cycle compression system, with an impulse at each revolution of the crank. It receives its charge and exhausts through a cylinder port opened and closed by the movement of the piston. A suitable valve regulates the charge received from the closed crank chamber in which the mixture is compressed by the downward stroke of the piston. Vapor and air are drawn into the crank case by the upward stroke of the piston, and thoroughly mixed by the motion of the crank. The engraving shows the circulating pump used for marine purposes, but the pipe leading from the pump to the water jacket is omitted. On the stationary engine a tank is used instead of a pump.



PALMER 1 H. P. GAS ENGINE.

The height of the stationary engine is 23 inches and that of the marine is 17 inches. The height from the base to the center of the shaft is 4½ inches. The weight of the marine engine is 135 pounds; of the stationary, 200 pounds.

The engine illustrated will run a 16 or 18-foot boat or light motor carriage. The company also build a ¾ h. p. engine.

A. K. WARREN & CO. CATALOGUE.

The new catalogue just issued by A. K. Warren & Co., 451 and 453 Greenwich street, New York, is well calculated to elucidate clearly the line of goods which this company carries. We find in it, described and illustrated, every article employed in a lighting or power installation from generator to lamp, or from the source of power to the motor, only the latest and most approved material being enumerated.

In getting up the catalogue the old-time index has been dispensed with; to make reference sure and easy, however, the various apparatus has been grouped in alphabetical order, a plan which by trial we find to work exceedingly well. Besides the apparatus illustrated we note a number of excellent full-page half-tone views of the various departments in the company's factory, which prove it to be excellently equipped for its work.

THE TRIUMPH ELECTRIC CO.'S CATALOGUE.

THE TRIUMPH ELECTRIC COMPANY, of Cincinnati, O., have just issued an exceedingly well gotten up catalogue of their apparatus, which affords a most convincing proof of their ability to turn out first-class apparatus. We note among the excellent illustrations views of many actual plants in which the Triumph direct connected apparatus for lighting, street railway and general power purposes is employed, as well as their marine set.

Besides the standard apparatus we find several illustrations of special machines, among them a mining machine and a cloth cutter. The company also build elevator motors and controllers, views of which are given.

A table at the end of the catalogue gives complete data of sizes, capacity, etc., of the company's machines.

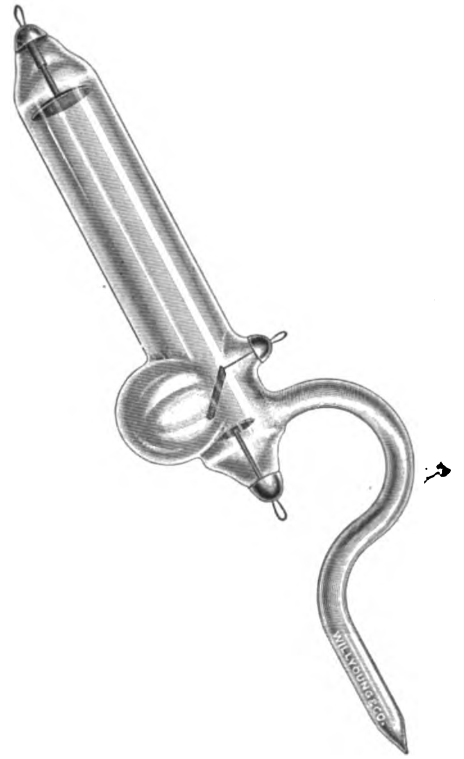
"BOWDOIN" X-RAY TUBES.

MORE than a year ago Profs. Hutchins and Robinson, of Bowdoin College, conducted some important experiments with X-ray tubes, and, as a result, developed a very efficient type which has since been largely used by both physicists and physicians. As the inventors were too much occupied with their professional duties to engage in the business enterprise justified by the merits of these tubes, an agreement was made with Messrs. Willyoung & Co., Philadelphia, to manufacture them in conjunction with and as part of their "W—S" X-ray plants.

The "Bowdoin" X-ray focus tube differs essentially from others in having a fluorescent material fused into the inner surface of the thin glass bulb; which not only tends to constancy of vacuum, but also secures a magnificently clear definition with the fluoroscope or in radiography. Also, the electrodes are so arranged that the reflector plate is not connected to a terminal, but merely acts as an obstacle to the bombarding rays; the anode being a disc at the end of the tube away from the cathode. This plan almost entirely prevents blackening of the glass from deposited platinum, however long the tube may be used.

Apart from remarkable definition the most important feature of the "Bowdoin" tube is the small amount of energy required to fully excite it, the claim being confidently made that a tube of this make energized by a 4-inch spark Willyoung induction coil will produce results that can only be approached by other apparatus of at least 50 per cent. greater capacity.

During the past two months changes have been made in design and dimensions of the Bowdoin tubes, thus making them better than ever; and at the same time because of largely increased output, it has been possible to materially reduce prices —a fact of utmost importance, in view of the fragile nature of all X-ray tubes.



WILLYOUNG & CO.

THE BOWDOIN X-RAY TUBE.

Mr. James G. Biddle, 910 Drexel Building, Philadelphia, is sole agent for Bowdoin tubes, as for all apparatus made by Willyoung & Co., and will gladly supply further particulars to interested parties.

WESTERN NOTES

THE WALKER CO., of Cleveland, have appointed Mr. W. R. Mason, 1202 Fisher Building, Chicago, their agent for the State of Missouri. He will open an office in St. Louis in the near future. The Walker Company are to be congratulated upon securing the services of Mr. Mason as one of their representatives, as his progressive work is well known in the West, where he has a host of friends among the electrical fraternity.

H. M. UNDERWOOD & CO., Marquette Building, Chicago, have appointed the Brewster Engineering Company, Thames Building, New York, sales agents for their duplex lamp guards in the East, with the exception of the New England States and Pennsylvania. The concern have had a number of inquiries for the Cloos junction box and report that the demand for this box is increasing and that the prospect of large sales in the near future is very good.

J. J. NORMAN COMPANY, 52 South Clinton street, Chicago, manufacturers of the Chicago Gas and Gasoline Engine, were closed up by the sheriff on June 18, by order of the Cook County Circuit Court, where three writs, in the names of Sophia Zerwnel, Anna Wolf and Philomena Kinderbusch, had been given against the company. Henry J. D. Wodeich has been appointed receiver for the concern. All the stock in trade and fixtures of the company will be sold on Tuesday, June 29.

THE AMERICAN RHEOSTAT CO., of Milwaukee, have recently sold through Kohler Bros., their Chicago agents, a number of rheostats for export to Japan, and have just sent a 50 h. p. overload starter to Liege, Belgium. They are at work on some new apparatus, which will soon be ready for the market.

SOLDERING FLUX for electrical work has been put on the market in a variety of different shapes. The latest thing in this line is Highland insulating soldering paste, which is being marketed by the Electric Appliance Company. Great claims are made for this paste on account of its convenience and non-corrosive qualities. The Electric Appliance Company are prepared to send small sample boxes of this paste to the trade on application, as they feel confident that its merits will bring business where it has once had a test.

NEW ENGLAND NOTES

L. A. CHASE & COMPANY. In our issue of June 16th on page xxxvi of the advertising pages, an unfortunate error crept in, whereby in the advertisement of L. A. Chase & Co., Boston, instead of printing an illustration of the Elden circuit breaker a cut was shown illustrating a switch of another make. It was probably apparent to all our readers that the cut was an error, but we wish to call particular attention to it.

CLARKE MOTOR CO. has been formed at Portland, Me., for the purpose of manufacturing electric motors. The capital stock is $1,000,000. The officers are J. W. Briggs, president, and G. A. Clarke, treasurer, both of Boston.

THE HOLTZER-CABOT ELECTRIC COMPANY have removed their business offices from their former location, 92 Franklin street, Boston, to the factory building, Station street, Brookline, to which place they request all communications to be sent hereafter.

PHILADELPHIA NOTES

THE LANGHORNE ELECTRIC LIGHT AND POWER COMPANY, Langhorne, Pa., has recently increased its electric light plant by adding a 200 h. p. engine built by the Ball Engine Company, Erie, Pa., being the third engine of this manufacture placed in this plant.

THE WAINWRIGHT BREWING COMPANY, Pittsburg, Pa., have recently installed an 80 h. p. engine, built by the Ball Engine Company, Erie, Pa. The engine is direct connected to General Electric dynamo.

MR. WARDELL JUKES, formerly with the United Electric Improvement Company, of Philadelphia, will represent the Shelby Electric Company, handling for them the Shelby incandescent lamps in that city and vicinity.

NEW YORK NOTES

MR. JOHN FINNEY, of Rochester, N. Y., has been chosen as superintendent of the Canandaigua electric light and street railway plant.
